WILSON, H. P. C., 709, 742.
WOODBURY, F., 515.
WOOD, H. C., 104.
WOODS, H., 488.
WYETH, J. A., 93.

ZINKE, E. G., 673.

INDEX.

Abattoir, methods of slaughtering animals of, 584, 590.
Abdomen; visceral injuries of, 369; pistol-shot wound of, 418, 739.
Abdominal; gestation, 118; muscles, spasmodic contraction of, 473; cavity, death from hemorrhage into, 624; galvanization, 630.
Abnormal mobility of tongue, 159, 211.
Abnormalities of aorta, 686.
Abortion; habitual, 305; imperfect, 625.
Abortive treatment of syphilis, 281.
Abscess; of cellular tissue, 39; pelvic treatment of, 71; pneumonic, 110; mammary, prevention of, 153; of the kidney, 218; renal, 411; acute fæcal, 432; simulating uterine fibroid, 537; of nasal septum, 616; of pancreas, 632.
Abscesses; pelvic, treatment of, 336; of spermatic cord, 472.
Absence; congenital, of lung, 155; of one testicle, 474.
Accidents, railroad, nervous diseases after, 565.
Acetate of lead, injurious influences of, 308.
Acid; anisic, an antipyretic, 90; carbolic, injection of, 219; nitric, poisoning, 247; indigestion, 571; disinfecting, 407; freckles, 697; osmium, in neuralgia, 438; boric, in cystitis, 476; lactic, in pathogenic tissues, 495.
Acne, bromide of arsenic in, 473.
Acorn chocolate for diarrhœas, 91.
Aconite poisoning, 583.
Acute; febrile glycosuria, 90; pemphigus, 570; inflammation of occipito-atlantal joints, 178; catarrhal nephritis, 222, 230; endocarditis, 201; rheumatism, treatment of, 282, 760; catarrhal laryngitis, 365; dementia, case of, 388; tonsillitis, treatment of, 411; fæcal abscess, 442; primary suppurative nephritis, 493.
Adenoma, 298.
Address at commencement, 515.
Adherent fallopian tube, ovary with, 457.
Adhesive properties of plaster, to increase, 448.
Administration; of hypnone, 187; chloroform, 464.
Adonidine, 374.
Adulteration; of food products, 28, 607; of olive oil, 346; of lard, 382.
Affections; of eye and spinal curvature, connection between, 119; of rectum, 403.
Ague, brass founder's, 507.
Air-baths, compressed, treatment with, 411.
Albuminuria, 676, 711, 717; treated by fuchsine, 83; cyclic, 537; diet in, 697; due to scarlet fever, 726.
Alcoholic hallucinations, 43.
Alcoholism, 631.
Alimentation, Germain Sée in, 47.
Altitudes, quinine in high, 93.
Alum gargles upon teeth, effects of, 697.
Amblyopia, hemorrhagic, cured by dilatation, 17.
Amblyopia and monoplegia, 539.
Ambrosia artemisiæfolia, hæmostatic properties of, 88.
Amenorrhœa, 568; santonin in, 188.
American Pasteur Institute, 95.
Ammonia in anthrax and carbuncle, 185.
Amputation of arm, 418; of breast, 523; of uterus, 651; of uterus, ovariotomy with, 685.
Amusing the insane, 445.
Anæsthesia; Esmarch's bandage in, 690; of hand, 690.
Anæsthetic; new local, 500; nitrous oxide an, 761.
Anæsthetics, 340; deaths from, 479.
Anæsthetization, prolonged, 71.
Anomalous lung, 206.
Anemia, 199.
Aneurism, 481; double popliteal, 154; dissecting of aorta, 377; occurring in stump, 466; traumatic inguinal, 535, 690.
Animals as medical practitioners, 241; slaughtering, methods of, 584, 590; respiratory changes in, 669.
Anisic acid an antipyretic, 90.
Ani, fistula in, 297.
Anodyne, cutaneous, 58.
Anteflexion, non-medical treatment of, 809.
Antetragus, congenital tumors of, 176.
Anthrax, ammonia in, 185.
Antidote to cocaine poisoning, 790.
Antidotes for poisons, 557.
Antipyrin, 183; influence of, 147, 495; in tuberculosis, 246; unpleasant effects of, 246; in pneumonia, 371; in malarial fevers, 568.
Antipyretic treatment, 462.
Antisepsis in the German army, 87.
Antiseptic incision, 409; mouth wash, 443; surgery, 511; amputation of breast, 523; in obstetrics, 547; vaginal injections, 673, 679.
Antiseptics in midwifery, 223.
Anus; fissure of, 404; imperforate, 618; artificial, 716.
Aorta; dissecting aneurism of, 377; abnormalities of, 686.
Aparine, galium, in psoriasis, 476.
Apartments, disinfection of, 155.
Aphonia from morphia, 476.
Apparatus for applying heat and cold, 411.
Apparent hydrophobia, 542.
Appendix vermiformis, melon seed in, 471.
Application of iodoform in diphtheria, 537.
Applicators, uterine, 267.
Arm; amputation of, 418; paralysis of, 684.
Anus, pruritus of, 540.
Arsenic habit, 383; bromide in acne, 473.
Arsenical wall papers in malarious regions, 383.
Arterial ligation a prophylactic measure, 112.
Arteries after ligature, changes in, 171; coronary, 493; iliac, ligature of, 535; ligature of, 690.

Artero-capillary; fibrosis, 221; capillary fibroid kidney, 538.
Artery, vertebral, wound of, 50.
Arthritis; rheumatoid, 44; of knee, 72; from peripheral nerve lesions, 283; chronic rheumatic, 663.
Artificial eggs, 446; honey, how to distinguish, 447; cocaine, 543; respiration, 622, 663; eruptions of the skin, 722.
Ascites; thrombosis of portal vein with, 9; permanent drainage in, 398.
Asiatic cholera, 189.
Aspiration in distention of gall-bladder, 506.
Assimilation in febrile patients, 147.
Association of Physicians and Pathologists, 319.
Ataxia, locomotor, weighted shoes in, 312.
Atlantic City in spring, 542.
Atresia, traumatic, of cervix uteri, 522.
Atrophoderma pigmentosum, 243.
Atropine, influence of, 310.
Attack on Pasteur, 127.
Auditory meatus, external, 67.
Angioma, congenital, 56.
Angiomata, cure of, 761.
Aural polypi; treatment of, 219; catarrhal inflation of the eustachian tube in, 295.
Auscultation; discovery, 127; diagnosis by, 163.
Ante-mortem heart clots, 175.
Automatism; epileptic, 402; phenomena, 489.
Autopsies on drunkards, 207.
Azoturia, 313.

Babies, respiratory croaking of, 344.
Bacilli, tubercle, 245.
Bacteria, gas-forming, 531.
Bacterio-therapeutics, attempt at, 373.
Bacteriology of certain eye diseases, 82.
Bacteriotherapy, 697.
Balata, 383.
Barometer a guide to health, 186.
Bastardy case, 28.
Baths: cold saline, on fevers, 18; hot, in nephritis, 26; in typhoid fever, 179; salt water, 186; gonorrhœal infection from, 414.
Battey's operation, pathological specimens from, 459.
Bee-stings, remedy for, 413.
Beef extracts, nutritive value of, 580, 614.
Beer, lager, 383.
Berlin University, medical faculty of, 250.
Belladonna; rash, 188; in cholera infantum, 283; effects of, 785, 807.
Benzoate of sodium in cholera infantum, 694.
Bichloride of mercury and urea for syphilis, 345.
Blackwater fever, treatment of, 88.
Biniodide of mercury, an antiseptic, 547, 679.
Bladder; multiple myoma of, 175; exstrophy of, 388; digital exploration of, 391, 429; gall-, distention of, 506; stone sacculated in the, 751.
Blind, increase of, 281.
Blindness, sudden, during labor, 572.
Blood; letting extraordinary, 249; poisoning, pyæmia or, 292; vessels, influence of cocaine on, 310; vessels, influence of antipyrin, 495; effect of removal of spleen on, 628.
Bloody urine in pregancy, 168.
Boat-racing injurious? 597.
Bodies, foreign, in vitreous, 427.
Body, foreign, in eye, 304.
Boric acid in cystitis, 476.
Boston water supply, 64.
Bowel, mortified, recognition of, 400.
Boy, gastrostomy in, 215.
Brain; compression of, 280; bullet in, 347; removal of, 554; tumor, case of, 587.
Brandy, flavoring principles of, 574.
Brass-founder's ague, 507.
Breath, gangrenous, relief of, 444.
Breast; cancer of, 50; carcinoma of, 396; antiseptic amputation of, 523.
Breasts, supernumerary. 505.
Breech presentation, complicated by large scrotum, 346.
Bright's disease, 232, 265; delirium of, 95; deafness in, 275; jaborandi, 282; urine in, 476; why so fatal, 730.
Bromide of arsenic in acne, 473.
Bronchial diseases, treatment of, 227.
Bronchitis; chronic treatment of, 147; treatment of, 377; fœtid, 570.
Bronchus, extraction of foreign body from, 57.
Bubo, chancrous, 179.
Bullet; extractor, improved, 167; in her brain, 347.
Burials, tax on, 318,
Burn, 297; by electric lamp, 338.
Burn-Bræ hospital for mental diseases, 542.
Burns of face, 339.
Bursal tumors, 474.
Buttock, erysipelas from injury to, 417.

Caffeine, influence of, 310.
Calcareous degeneration of fibroid tumor of, 334.
Calcium, chloride of, 474.
Calomel in pneumonia, 371.
Calculus; vesical, case of, 112; renal, 659.
Camphor intoxication, 177.
Cancer; of breast, 50; of cervix, 167; influence of diet on, 238; of œsophagus, 268; prophylaxis of, 349; mammary, 479; of lung, 658; of uterus, 658.
Cancer; uterine, treatment of, 695; of stomach, prognosis of, 791.
Cancerous inheritance, theory of, 18.
Carbolic acid; injection of, 219; disinfecting, 407; in indigestion, 571; in freckles, 697.
Carbuncle; ammonia in, 185; treatment of, 188; cured by gonorrhœa, 696.
Carcinoma; primary, 208; of breast, 396.
Cardiac disease, high altitudes on, 668.
Caries of tibia, 329.
Case; of empyema, 12; of pemphigus, 19; of poisoning by datura stramonium, 25; an instructive, 25; of vesical calculus, 112; of hermaphrodite, 114; of superfœtation, 142; of syphilitic phthisis, 147; of intermittent fever, 176; of quintuple labor, 178; of dystocia, 198; of perityphlitis, 165, 205; of intestinal malformation, 210; of empyema, 218; of persistent menstruation, 283; of intussusception, 359; of intubation of larynx, 365; of reflex vaso-motor neurosis, 370; remarkable, 383; of acute dementia, 388; of wiring fractured patella, 421, 425; of obscurity in detecting foreign bodies, 433; of lead poisoning, 439; of perforation of vermiform appendix, 442; of diabetes insipidus, 442; of chylous urine, 442; of prolapse of rectum, 443; of dystrophy of thumb joints, 443; of laceration of cervix uteri, 455; of ossification of the choroid, 460; of scarlet fever and measles, 468; presenting cataleptoid

symptoms, 489; of necrosis of vomer, 418; of tuberculosis of skin, 506; of pons oblongata transitiva, 523; of rigor in epileptic, 531; of reproduction of femur, 538; of multiple myomata, 539; of general paresis, 554; of ruptured ovarian cyst, 554; of antidotes for poisons, 557; of gunshot wound, 559; of brain tumor, 587; of stramonium poisoning, 594; of insanity, 609; of median nerve suturing, 618; of mitral stenosis, 621; of vesico-vaginal fistula, 622; of imperfect abortion, 625; of protracted labor, 626; of traumatic nephrosis, 629; of narrowing of small intestines, 631; of removal of lower jaw, 649; of tubal pregnancy, 657; of renal calculus, 659; of trichinosis, 686; of median nerve suturing, 697; of artificial anus, 716; of intercurrent hepatitis, 719; of post-partum hemorrhage, 745; of infection in utero, 761.
Catalepsy, 206; hystero-, 108.
Cataleptoid systoms, case presenting, 489.
Cataract extractions, 461.
Catarrh; hepatic, 107; aural, in young children, 295; nasal headaches with, 489; chronic nasal, 727.
Catarrhal phthisis, treatment of, 147; acute nephritis, 230; acute laryngitis, 365; icterus, treatment of, 470; fever simulating typhoid, 642; metritis, iodoform in, 727.
Catgut suture of patella, 600.
Catheter, a prostatic, 91; syphilis, transmitted by, 539.
Cavities, internal, dry dressing for, 339.
Cause of reflex nervous phenomena, 375; of pleurisy, 467.
Causes and treatment of quinsy, 465; of consumption, 667.
Cellular tissue, abscess of, 39.
Cerebral tumors, difficulties of diagnosis in, 240; substance, fracture of skull with loss of, 252; hemorrhage, sudden fatal, 257; embolus, 267; manifestations in mumps, 340; syphilis, 561, 571, 632.
Cerebellar softening, 662.
Cerebri, hernia, treatment of, 593.
Cerebro-spinal fever, epidemic of, 376.
Cervical canal of womb, dilatation of, 91; spinal cord, 588.
Cervix uteri, wound of, 154; cancer of, 167; hypertrophic elongation of, 168; uteri, laceration of, 455; uteri, traumatic atresia of, 522; laceration of, 630.
Chancrous bubo, 179.
Charlatan's advance agent, 446.
Chemical garden, 574; basis of water, 783.
Chicken-pox, eruption following, 563.
Chilian remedy for cystitis, 25; treatment of lienteric diarrhœa in, 119; optic neuritis in, 155; prevention of myopia in, 312; peculiarities of malaria in, 475; headache in, 501; nursery for, 638; diseases of, 667; insomnia in, 694; morphine in eclampsia of, 697; deaf, treatment of, 737; proper diet for, 786.
Childhood; infectious vulvo-vaginitis of, 279; scrofula in early, 504.
Chlorate of potassium, poisoning by, 305.
Chloroform or ether after cocaine, 92; a cheaper, 448; administration of, 464.
Chloral on digestion, influence of, 152.
Chloride of gold and sodium in pertussis, 120; stannous. disinfectant value of, 447; of calcium, 474.
Chocolate, acorn, for diarrhœas, 91.
Cholera, 572; infantum, belladonna in, 283; benzoate of sodium in, 694; treatment of, 378; Asiatic, 189; in Barcelona, 211; again, 598; in Italy, 734; in Gibraltar in 1885, 735; epidemic, 735.
Cholesterine in retina, 507.
Chorea minor from naso pharyngeal reflex, 509.
Chronic bronchitis; treatment of, 147; ulcers, 156; cirrhotic kidney, 230; ulceration of face, 250; dysentery, 268; simple ulcers, 311; meningitis, 394; kidney disease, diagnosis of, 437; ulcers, treatment of, 463; Bright's disease, urine in, 476; endocarditis, 493; nephritis, nitro-glycerine in, 569; tetanus, symptoms of, 559; rheumatic arthritis, 663; nephritis, milk diet in, 728; diarrhœa, remedy for, 743; cystitis, 773.
Chylous urine, 442.
Chylothorax, 280.
Cider and rheumatism, 319.
Circumcision, 236.
Circumstantial evidence, 253.
Cirrhosis ? of liver in a child, 54.
Clavicle, fractured, method of treating, 567.
Cleanliness, 446.
Cleaning powder for windows, 447.
Clinical; lecturers, 22; diabetes, 642; thermometers, 602.
Club-foot; management of, 222; treatment of, 792.
Cocaine; habit, 13; salicylate in neuralgia, 26; in whooping-cough, 91; ether or chloroform after, 92; on the central nervous system, effects of, 132, 140; and hay-fever, 135; effects of, 150; in vaginismus, 248; about, 282; influence of, 310; spray, cause of laryngeal spasm, 376; in gastralgia, 379; in affections of eyes, 411; treatment of morphine habit with, 439; decline in, 446; discovery of, 478; in neuralgia, 508; artificial, 543; in vaginal operations, 572; tests for, 601; in hay-fever, 729; in retention of urine, 752.
Coffee; eating habit, 412; a disinfectant, 409; and pruritus, 725.
Coincidence, diagnosis by, 473.
Coition; death from, 108; vulvo-rectal fistula from, 776.
Cold; saline baths on fevers, 18; apparatus for applying, 411; prophylactic measures against, 475.
Colles's fracture, 755.
Colloid degeneration of skin, 498.
Colon, narrowing of, 762.
Colorless tincture of iodine, 694.
Coma, diabetic, 91.
Comminuted fracture of head of tibia, 343.
Commissions or inquisitions in lunacy, 65.
Concealing taste of quinine, 278.
Conception while uterus contained a placenta, 247.
Confinements; shortest interval between, 192; short interval between, 316.
Congenital; angioma, 56; absence of lung, 155; tumors of the antetragus, 176; malformation of eyes, 209; deformities and maternal impressions, 248; absence of left kidney, 335; dislocation of hip-joint, 513; malformation of hands, 535; deficiency of tubes, 712; strictures of rectum, 720.
Conjunctivitis, 139.

Consciousness, loss of, 257.
Constipation, habitual, treatment of, 113.
Consultation, novel, 317.
"Consummatus est," 22.
Consumption, causes of, 667.
Complete rupture of kidney, 601.
Complicated labor, 624.
Compound fracture of patella, 506.
Compressed air-bath, Meniere's disease treated by, 411.
Compression of the brain, 280.
Compulsory vaccination, 29.
Contagious; period of syphilis, limitation of, 223; ophthalmia in public institutions, 237.
Contraction; of lung, displacement of heart due to, 199, 205; spasmodic, of abdominal muscles, 473.
Contractions of external auditory meatus, 67.
Contracture, Kernig's, of lexion, 566.
Contributions to practical surgery, 240.
Control of hemorrhage, 306.
Convergent strabismus, treatment of, 314.
Convulsions, infantile, 760.
Coughing, unusual cause of, 632.
Cord; umbilical, ligating the, 157; ligating the, 347; tying the, 603.
Cornea, foreign bodies upon, 450.
Corpus, galvanized, 414.
Correction, 254, 285.
Corrosive sublimate; disinfection with, 155; sublimate, danger from, 475; sublimate in diphtheria, 688.
Cranium, human, civilization of, 701.
Craniotomy, 422.
Cremation, 638; in France, 574.
Croaking, respiratory, of babies, 344.
Croup; membranous, 73, 283, 452; spasmodic, complicating measles, 148; diphtheritic, 336.
Croupous pneumonia of lung, 568; and hypostatic pneumonia, 596.
Curative potency of prolonged sleep, 218.
Cure of stammering, 95.
Curvature, lateral, of spine, 72; spinal, 570.
Cutaneous anodyne, 58.
Cyst; retention, 335; ovarian, ruptured, 554.
Cystic degeneration of kidneys, 174; kidney, 206; albuminuria, 537.
Cystitis; Chilian remedy for, 25; boric acid in, 476; chronic, 773.
Cysts; perinephritic, 174; surgical, treatment of, 310.
Cysto-sarcoma, pregnancy mistaken for, 313.
Cystotomy, kolpo-, 617.

Daltonism amongst railway officials, 511.
Damages for dead body, 253.
Darwin's doctrine of evolution, 304.
Datura stramonium, poisoning by, 25.
Deaf mutes, 120; increase of, 281; children to parents of, 737.
Deafness in Bright's disease, 275.
Death from attempted coition, 108; from round worms, 187; by hemorrhage, 408, 624; from dyspnœa, 441; from perityphlitis, 471; by hanging, diagnosis of, 508; from croupous pneumonia, 568.
Deaths from anæsthetics, 479.
Debove's "cramming" or "forced feeding" system, 701.
Decapitated head, how long does it retain sensibility, 213; experiments on, 789.
Decline in cocaine, 446.
Decoction of lemons in intermittent fever, 599.
Defibrinated blood, injection hypodermically of, 26.
Deformed penis, 537.
Deformities, congenital and maternal impressions, 248.
Degenerated kidney, 557.
Degeneration, cystic, of kidneys, 174; of ovaries, 333; colloid, of skin, 498.
Delegates, a word to, 405.
Delirium of Bright's disease, 95.
Delusions from intestinal accumulations, 687.
Dementia, acute, case of, 388.
Dental irritation, lagophthalmos due to, 19.
Dentists, bogus, 286.
Dentition in infantile pathology, 502.
Deobstruent, glandular, chloride of calcium as, 474.
Desquamative prostatitis with hyaline casts, 276.
Destruction of microbes by heat, 696.
Determination of sex of fœtus, 187.
Diabetes, 52; lagopthalmos in, 27; sudden origin of, 88; insidious onset of, 89; cure in, 90; mellitus, 207, 563; insipidus, 442; clinical, 642; on gestation, 728; insipidus, valerian in, 762; mellitus, treatment of, 809.
Diabetic coma, 91.
Diagnosis; in ulcer, 80; of pregnancy, 136; by auscultation, 163; of cerebral tumor, difficulties of, 240; of gonorrhœa in females, 314; of twins, 429; in chronic kidney disease, 437; by coincidence, 473; of neurasthenia, 521; of spinal tumors, 552; of small-pox, 559; of fibro-cystic tumor, 651; of cancer of uterus, 658; of pregnancy, 678; tuning fork in, 686; by hanging, 698; of lead-poisoning, 761.
Diagnostic signs of pregnancy, 74.
Diaphragmatic pleurisy, 399.
Diarrhœa; acorn chocolate for, 91; lienteric in children, treatment of, 119; white of egg in, 728; chronic, remedy for, 743.
Diet on cancer, influence of, 238; in albuminuria, 697; for children, 786.
Differentiation, pneumatic, 461.
Digestion, influence of chloral on, 152; of food on, 351; and dyspepsia, 526.
Digestive tract, gas-forming bacteria of, 531; ferments, therapeutic use of, 562.
Digital exploration of bladder, 391, 429.
Dilatation of sphincter ani, 17; of cervical canal of womb, 91.
Diphtheria, 476; complicating syphilis, 79; new remedy in, 151; cured by tolu varnish, 185; treatment of, 221; new treatment of, 471; and pigeon-keeping, 479; manure heaps and, 507; iodoform in, 537; not sewer-gas disease, 656; corrosive sulimate in, 688.
Diphtheritic paresis, 203; croup, 336; inflammation, 626.
Dipsomania, strychnine in, 727.
Disinfectants, 656; value of stannous chloride, 447; coffee as, 469; iodol, 567.
Disinfecting influence of carbolic acid, 407.
Disinfection of hands, 56, 478, 791; of rags, 126; of apartments, 155; by salt-water stove, 286; new method, 374.
Dislocation of ungual phalanx of thumb, 186; partial of head of radius, 214; of humerus, 343, 785; congenital of hip-joint, 513; of shoulder-joint, 500.

Discovery; of auscultation, 127; of cocaine, 478.
Disease; finger nails in, 41; Bright's, delirium of, 95; of umbilicus in new-born, 184; a new, 186; mastoid, 206; Bright's, 232, 265; Bright's, deafness in, 275; Bright's, jaborandi in, 282; kidney, 305; finger nails in, 395; Meniere's treatment of, 411; chronic kidney, diagnosis of, 437; chronic Bright's, urine in, 476; a strange, 511; syphilitic, 588; tubercular, of spinal cord, 619; cardiac, high altitudes on, 668; Hodgkin's, 721; Bright's, why so fatal, 730; hair roots as indicators of, 754; Pott's, of spine, 769; ear, meningitis after, 783; of skin, 809.
Diseased kidneys, death from, 497.
Diseases; eye, bacteriology of, 82; of the respiratory organs, 117; of eye, relationship of, 345; infectious, medical risks from, 349; of skin, lanolin in, 419; of heart and kidneys, habitual abortion in connection with, 475; skin, resorcin in, 591; nervous, after railroad accidents, 565; of children, 667.
Displaced spleen and pregnancy, 242.
Displacement; of heart, 199, 205; uterine, cause of, 527.
Disposal of sewage, 325, 353.
Dissecting aneurism of aorta, 377.
Distention of gall bladder, 506.
Distocia, discussion on, 427.
Diuretics, Russian, 626.
Doctor; Bond and Benj. Franklin, 62; Graves, case of, 95; peculiar danger, 158; surplus of, 213; E. O. Shakespeare, 287; Ramsey's revolver, 383; Nebinger's estate, 638; Flint's successor, 703.
Dod's spray, management of, 63.
Double; popliteal aneurism, 154; battledoor placenta, 429.
Dover's solution, 347.
Drainage; of pelvic abscesses, 71; permanent, in ascites, 398.
Douching infants, 786.
Dressing; new, for wounds, 57; dry, for internal cavities, 339; dry, 440.
Drinking; largely, philosophy of, 78; water, lead poisoning from, 273.
Dropsy, peritoneal, 709, 742.
Druggists warned, 255.
Drugs, explosive, 509.
Drunkards, autopsies on, 207.
Dry dressings, 440; for internal cavities, 339.
Duct, Steno's, occlusion of, 397.
Ductus arteriosus, changes in, 171.
Dumb, increase of, 281.
Dust; inhalation of, 182; of London, 509.
Datura stramonium, poisoning by, 241.
Dysentery; chronic, 268; ergot in, 793.
Dyspepsia; atonic, sour milk in, 55; yellow oxide of mercury in, 89; and digestion, 526; papaïn in, 752.
Dyspnœa; hysterical, 109; death from, 441.
Dystrophy of thumb-joints, 443.
Dystocia; case of, 198; cause of, 303.

Ear; hygiene of, 223; lesions of, 686; removal of foreign bodies from, 697; disease, meningitis after, 783.
Eclampsia of children, morphine in, 697.
Eczema, 675.
Eczematous eruption, 238.

Hemicrania, 155 ; operation for, 630.
Hemiglossitis, 631.
Hemiplegia ; syphilitic, 216 ; rare symptoms in, 348 ; total trigeminal paralysis with, 681.
Hemorrhage ; from rupture, 115 ; from wound of cervix uteri, 154; post-partum, strychnia in, 249 ; cerebral, sudden fatal, 257 ; control of, 306 ; death by, 408, 624; meningeal, 618 ; post-partum, 745.
Hemorrhagic amblyopia cured by dilatation, 17.
Hemorrhoidal tumors, treating of, 432.
Hemorrhoids in pregnancy, treatment, 223.
Catarrh, 107 ; origin of urea, 569.
Hepatitis ; chronic, yellow oxide of mercury in dyspepsia due to, 89 ; intercurrent, 719.
Hereditary ; syphilis, 417, 435 ; tremors, 729.
Hemanæsthesia, hysterical, 23.
Hermaphrodite, case of, 114.
Hernia ; partially descended, 335 ; strangulated, operation for, 400 ; trusses in, 410 ; abscess of spermatic cord simulating, 472 ; radical cure for, 558 ; cerebri, treatment of, 593 ; inguinal, radical cure of, 617.
Herniotomy, 582.
Herpes of pharynx, 250.
Heresies, obstetrical, 2.
Hip-joint ; congenital, dislocation of, 513 ; chronic rheumatic arthritis of, 663.
Hodgkin's disease, 721.
Home treatment of inebriates, 771.
Honey ; poisonous, 448 ; artificial, how to distinguish, 447.
Hospital Reports—
Children's Hospital of Philadelphia.—
Clinic of Dr. J. Ashhurst, 72.
Jefferson Medical College Hospital.—
Clinic of Dr. J. T. Parvin, 11, 73, 168, 267.
Clinic of Dr. W. Thomson, 139.
Clinic of Dr. R. Bartholow, 202, 268, 360.
Pennsylvania Hospital.—
Clinic of Dr. M. Longstreth, 41, 393.
Clinic of Dr. T. G. Morton, 43.
Clinic of Dr. J. M. Da Costa, 43, 199.
Clinic of Dr. J. H. Hutchinson, 107, 230, 265.
Clinic of Dr. J. H. Packard, 329.
Philadelphia Hospital.—
Clinic of Dr. W. H. Parish, 39, 74, 167.
Clinic of Dr. J. W. White, 40.
Clinic of Dr. H. C. Wood, 104.
Clinic of Dr. T. Parvin, 136, 422.
Clinic of Dr. L. W. Steinbach, 295.
University of Pennsylvania.—
Clinic of Dr. W. Goodell, 9.
Clinic of Dr. W. Pepper, 9.
Clinic of Dr. D. H. Agnew, 297, 396.
Clinic of Dr. J. Ashhurst, 298.
Hot baths in nephritis, 26.
Household utensils, lead-poisoning by, 372.
Houses, living in newly-built, 309.
Humerus ; dislocation of, 343 ; fracture of, 385 ; necrosis of, 769 ; dislocation of, 785.
Human ; milk, new test, 119 ; triplets, 633 ; cranium, civilization of, 701.
Humerus, dislocation of the, 806.
Huxley on science and medical teaching, 157.
Hyaline casts, desquamative prostatitis with, 276.
Hydro- ; add pyo-salpinx, 333 ; salpinx, 362.
Hydrocele, 295 ; treatment of, 221 ; radical cure of, 409.
Hydrocephalus, 107.
Hydrogen, sulphuretted, poisoning by, 274.
Hydrophobia, 380 ; and Pasteur's remedies, 156 ; in Paris, 445 ; apparent, 542 ; Pasteur on, 689 ; in Austria, 729 ; in Russia, 786.
Hydrosalpynx, with congenital deficiency of tubes, 712.
Hygiene of the ear, 223.
Hygienic Institute in Berlin, 28.
Hyperpyrexia, post-mortem, 314.
Hypertrophic elongation of cervix, 168.
Hypertrophy ; of neck of uterus, 11 ; of the prostate, 412 ; of pons, oblongata transition, 523.
Hypnone, administration of, 187.
Hypnotic, a new, 346.
Hypodermic ; injections of salicylate of cocaine in neuralgia, 26 ; injection of oil, 54.
Hypodermically ; injection of defibrinated blood, 26 ; strychniæ, 443 ; of morphine, 697.
Hypostatic pneumonia, croupous and, 596.
Hysterectomy, vaginal, 778.
Hysteria, 44 ; treatment of, 29 ; in soldiers, 569 ; its relation to diseases, 784.
Hysterical ; hemianæsthesia, 23 ; dyspnœa, 109.
Hystero-catalepsy, 108.

Ice in sick-room, 415.
Ichthyol, its uses, 27.
Icterus, catarrhal, treatment of, 470.
Idiosyncrasy, quinine, 371.
Illegal ; practitioners of medicine, 342 ; practice, 533.
Ileum, stricture of, 56.
Iliac arteries, ligature of, 535.
Illinois State Board of Health and regulation of medical practice, 63.
Illusions, melancholia with, 202.
Impaction of fæces, 41.
Imperfect ; development of testicle, 474 ; abortion, 625 ; symmetry, 790.
Imperforate anus, 618.
Impregnation, unconscious, 753.
Impressions ; maternal, 248 ; mental, labor influenced by, 763.
Improved bullet extractor, 167.
Incarceration of melon seed, 471.
Incision ; antiseptic, radical cure of hydrocele, by, 409 ; in ovariotomy, size of, 538.
Incontinence, nocturnal, of urine, 571.
Increase ; of blind, deaf, and dumb, 281 ; of inebriety, 477 ; of life, 478.
Indigestion, carbolic acid in, 571.
Indirect cerebral syphilis, 571.
Inebriates, home treatment of, 771.
Inebriety, increase of, 477.
Infancy ; phimosis, 401 ; urticaria in, 754.
Infantile ; paralysis, 72, 759 ; pathology, dentition in, 502 ; menstruation, 511 ; convulsions, 760.
Infant ; feeding, 220 ; fracture of femur in, 387.

Infants; plea for weighing, 440; drenching, 786.
Infantum; cholera, belladonna in, 283; treatment of, 378.
Infarctions of kidneys, 175.
Inflammation; acute, of occipito-atlantal joints, 178; diphtheritic, 626.
Inflation of the Eustachian tube, 295.
Infection; gonorrhœal, from baths, 414; poisonous, prevention of, 438; of old gonorrhœa, 443; of tuberculosis, 444; in utero, 761.
Infectious; vulvo-vaginitis of childhood, 279; diseases, medical risks from, 349.
Influence; of temperature on life of fœtus, 94; of antipyrin, 147; of chloral on digestion, 152; of diet on cancer, 238; of operations on tuberculosis, 434; of kairin, 495.
Information from Pasteur, 255.
Inguinal; traumatic aneurism, 535; hernia, radical cure of, 617; aneurism, 690.
Inheritance, cancerous, theory of, 18.
Inhalation of dust, 182.
Inhalations in pulmonary tuberculosis, 570.
Injection; of defibrinated blood hypodermically, 26; of oil, hypodermic, 54; of carbolic acid, 219; in catarrhal icterus, 470; of iodo-glycerine, paralysis following, 567; of oil of turpentine, 761.
Injections; hypodermic, of salicylate of cocaine in neuralgia, 26; into the lungs, 287; of osmium acid in neuralgia, 438; vaginal antiseptic, 678, 679.
Injuries; visceral, of abdomen; 369; recent, suture of nerves of, 475.
Injurious? is boat-racing, 597.
Injuriousness of natural gas as fuel, 479.
Injury; sarcoma after, 15; of hand from machinery, 331; to buttock, erysipelas from, 417.
Inoculation; of tubercle, 443; preventive, 318; of yellow fever, 665.
Insane; medico-legal questions of, 33; amusing the, 445; asylums, female physicians in, 749; surgical affections in, 791.
Insanity, 104; cases, testimony in, 29; lectures on, 33, 65, 609; puerperal, 535; among New England farmers, 573.
Insidious onset of diabetes, 89.
Insipidus diabetes, 442.
Insomnia in children, 694.
Instructive case, 25.
Instruments, Staufer's, 318.
Insufficient food, effects of, 566.
Internal cavities, dry dressing for, 339.
International Medical Congress, 85, 94, 125, 149, 254, 375, 629, 701, 757, 766.
Intercurrent hepatitis, 719.
Intermittent fever; case of, 176; decoction of lemons in, 599.
Interstitial myocarditis, 493.
Intestinal; malformation, 210; obstruction, treatment of, 378, 663; accumulation, delusions from, 687.
Intestines, small, narrowing of, 631.
Intertrigo, treatment of, 184.
Intolerance of quinine and morphine, 599.
Intoxication, camphor, 177.
Intramural fibroids, 170.
Intubation of larynx, 365.
Intussusception, case of, 359; of upper part of jejunum, 466.
Invention, an important, 287.
Inversion; of temperature curve, 602; of uterus, 726.
Inverted toe-nail, 297, 476.
Iodine, colorless, tincture of, 694.
Iodo-glycerine, injection of, 567.
Iodoform; in diphtheria, 537; in chronic catarrhal metritis, 727.
Iodol, 24.
Iridectomy, 139.
Iris living in vitreous chamber, 235.
Iritis; syphilitic, 40; serosa to eye, 729.
Irritation; dental, lagophthalmus due to, 19; genital, cause of reflex nervous phenomena, 375.
Ivy-poisoning, treatment of, 762.

Jaborandi in Bright's disease, 282.
Jaw; lower, necrosis of, 536; removal of, 649.
Jejunostomy, 145; gastrostomy and, 48.
Jejunun-intussusception of upper part of, 466.
Joint, shoulder, dislocation of, 500.
Joints; rheumatic affections of, 219; sprained, 505.
Justice's first charge, 415.

Kairin, 183; influence of, 495.
Kernig's flexion contracture, 566.
Kharkoff, optic neuritis in, 89.
Kidney; sarcoma of, 77; cystic, 206; abscess of, 218; chronic cirrhotic, 230; disease, 305; left, congenital absence of, 335; disease, chronic diagnosis of, 437; rupture of, 507; fibroid-arterio capillary, 538; degenerated, 557; complete rupture of, 601.
Kidneys; cystic degeneration of, 174; infarctions of, 175; disease, habitual abortion of, 475; diseased, death from, 497.
King, a, who believes in antiseptics, 812.
Knee, arthritis of, 72.
Kolpo-cystotomy, 617.
Krull's injection in catarrhal icterus, 470.

Labor; quintuple, case of, 178; complicated by placenta prævia, 197, 203; treatment of, 270; sudden blindness during, 572; complicated, 624; protracted, 626; mitral stenosis in, 696; influenced by mental impressions, 763.
Labium, pedunculated growth of, 494.
Lacerated perineum of neck of uterus, 11.
Laceration; of perineum, 431; of cervix uteri, 455, 630.
Lactated food, 768.
Lactic acid, in pathogenic tissues, 496.
Ladies' tipple, 158.
Lager beer, 383.
Lagophthalmus; due to dental irritation, 19; in diabetes, 27.
Lanolin, 314, 557; new ointment, basis, 215; its use in skin diseases, 419; in ophthalmic practice, 454.
Laparotomy; in penetrating wounds, 369; of uterus, 651; treatment of intestinal obstruction by 663; for pistol-shot of abdomen, 739.
Lard, adulteration of, 382.
Larva of flea, 55.
Laryngeal surgery; results of, 48; recurrent, lesion of, 249; spasm from cocaine spray, 376; phthisis, pregnancy complicated with, 428.
Laryngitis, acute catarrhal, 365.
Larynx; intubation of, 365; fracture of, 408.
Latent pneumonia, 119.
Lateral curvature of spine, 72.

Laveran, malarial germ of, 427.
Lead poisoning, 97, 412, 439; from drinking water, 273; by household utensils, 372; diagnosis of, 761; tremor, 508.
Lecturers, clinical, 22.
Left and right-handedness, 81.
Legislation, sanitary, 183.
Lesions of the ear, 686.
Lemons in intermittent fever, 599.
Lens, ossification of, 460.
Leprosy in Japan, 223.
Lesion of the recurrent laryngeal, 249; pulmonary terpine in, 434; of the perineum, 665.
Leucorrhœa and purulent ophthalmia, 809.
Leucorrhoeal discharges from roller skating, 281.
Lewinin, new anæsthetic, 500.
Libraries, two large, 447.
Lienteric diarrhœa in children, treatment of, 119.
Life, increase of, 478; seat of, 756.
Ligaments, round, shortening of, 413; congenital deficiency of, 712.
Ligating the umbilical cord, 157; the cord, 347.
Ligature of arteries, 690; changes in, 171; of iliac arteries, 535.
Lightning, gas sulphur in, 318.
Limbs, saving condemned, 529.
Limitation of contagious period of syphilis, 223.
Lip reading, 351, 737.
Lithæmia, treatment of, 313.
Lithotomy, 40; supra-pubic operation of, 249.
Liver in young child, cirrhosis of, 54; sarcoma of, 174; cystic degeneration of, 174; metastasis to, 458; rupture of, 507.
Living in newly-built houses, 309.
Local paralyses, 42.
Locomotor ataxia, weighted shoes in, 312.
Longevity, remarkable instance of, 158.
London dust, 509.
Loss of consciousness, 257.
Lunacy, commissions or inquisitions in, 65.
Lung, congenital absence of, 155; contraction of, 199, 205; croupous pneumonia and gangrene of, 568; cancer of, 658.
Lungs, injections into, 287; treatment of tuberculosis of, 314: metastasis to, 458.
Lymphadenosis, 112.

Machinery, injury of hand from, 331.
Mackenzie's forceps, removal of fibroma by, 335.
Madrid, ovariotomy in, 119.
Magnet, removal of foreign body by, 562.
Magnetism, micro-organisms and, 575.
Malaria, unusual effects of, 242; in children, peculiarities of, 475.
Malarial, germ of laveran, 427; fevers, antipyrin in, 568; fever, 705.
Malarious regions, arsenical wall-papers in, 383.
Malformation, intestinal, 210; congenital, of eyes, 209; of hands, 505.
Malpraxis, treatment and suit for, 579.
Malignant nasal polypus, treatment of, 16; pustule, recovery from, 113.
Malthus' law and tumor-growth, 571.
Man, proper weight of, 415.
Mamma, supernumerary, 336.
Mammary abscess, prevention of, 153; cancer, 479.
Management of stray dogs, 63; of mental depression, 221.
Manicure, 784.
Manual training in United States, 447.
Manure heaps and diphtheria, 507.
Martyr of science, 470.
Massage of the thoracic organs, 154; sciatica cured by, 729.
Mastoid disease, 206.
Masturbation, treatment of, 760.
Maternal impressions, 248.
Measles; vaccination for, 119; spasmodic croup complicating, 148; and scarlet fever, 468; at Prussian court, 542; eruption following, 563; concurrence of, 645.
Meatus, auditory, external, 67; vascular tumor of, 267.
Median nerve, suturing, 618; nerve suturing, 697.
Medical staff in Germany, 30; practice, regulation of, 63; Congress, international, 85; teaching, Huxley on, 157; battery, a new, 159; prize questions, 190; testimony, 222; practitioners, animals as, 241; faculty of the Berlin University, 250; risks from infectious diseases, 349; exhibition in Berlin, 479; aspects of social questions, 725.
Medical Societies.

Obstinate vomiting cured by stomach-tube, 243.
Obstruction; aortic, and mitral regurgitation, 231; intestinal, treatment of, 378.

Occipito-atlantal joints, acute inflammation of, 178.
Occlusion of Steno's duct, 397.
Œdema; unilateral, 249; neuropathic, 344.
Œsophagotomy for foreign bodies, 633.
Œsophagus; cancer of, 268; diverticula of, 685.
Oil; hypodermic injection of, 54; of sassafras for neuralgia, 156; poisonous effect of, 345.
Ointment, basis, a new, 215.
Oleomargarine, 255, 542; manufacture, methods of, 350.
Olive oil, adulteration of, 346.
Onomatomania, 49.
Opacities before the eyes, 450.
Operate in empyema, when not to, 314.
Operation; for nasal polypus, 16; for pruritus vulvæ, 145; Porro's, in Japan, 159; for perityphlitis, 165, 205; for convergent squint, 219; supra-pubic, of lithotomy, 249; the royal, 444; for epithelioma of tongue, 449; for hemicrania. 630; Emmett's button-hole, 774.
Operations; for strangulated hernia, 400; on tuberculosis, influence of, 434; vaginal, cocaine in, 572.
Ophthalmia; contagious in public institutions 237; gonorrhœal, 718.
Ophthalmic; practice, lanolin in, 454; surgery, perfection of, 471.
Ophthalmology, address on, 664.
Opinion, the right to express your, 534.
Optic neuritis; in Kharkoff, 89; in children, 155.
Orbit; rare tumor of, 118; removal of splinter from, 488, 494.
Os calcis, necrosis of, 43.
Organisms; micro-, of syphilis, 116; and magnetism, 575.
Osmium acid in neuralgia, 438.
Ossification of choroid, 460.
Osteo-; arthritis, spinal sclerosis and, 601; plastic resection, 781.
Otology, progress, 120.
Ovale, patent foramen, 107.
Ovary; enlargement of, 74; hæmatoma of, 457.
Ovarian; tumor, 73, 716, 780; with twisted pedicle. 459; epilepsy, 280; displacement, 370; cyst, ruptured, 554; dropsy, 709, 742.
Ovaries; follicular degeneration, 333; extirpation of, 440; and tubes, 802.
Ovariotomy; in Madrid, 119; on menstruation, effects of, 216; size of incision in, 538; sponges in, 570; with amputation of uterus, 685; sequela of, 692.
Ozæna, remedy for, 153.

Packer's tar soap, 95.
Packing and hot baths in nephritis, 26.
Painless escharotic, 153.
Painful swallowing, treatment of, 56.
Panacea of modern gynecology, 539.
Pancreas; treatment of cysts of, 310; abscess of, 632.
Papain or payayotin, 220; in dyspepsia, 752.
Papilloma of hilum, 362.
Paraffin-oil, poisoning by, 534.
Paralysis; result of fall, 12; local, 42; uræmic, in the aged, 54; infantile, 77, 759; facial, 187; or spasm? 249; following injection of iodoglycerine, 567; of arm from injury, 684; Paris letter, 123, 791.
Parasite, pseudo of man, 55.
Parents of deaf children, 737.
Paresis, diphtheritic, 203; case of, 554.
Partially descended testicle, 335.
Parturient canal, diphtheritic inflammation of, 626.
Parturition, influence of diabetes on, 728.
Passage of gall stones, 361.
Passion, the sexual, 169.
Pasteur, 126, 127; American Institute, 95; remedies and hydrophobia, 156; information from, 255; on hydrophobia, 689.
Pastry, vaseline, 127.
Pathetic picture, 125.
Patella; fractured, wiring of, 421, 425; compound fracture of, 506; catgut suture of, 600.
Pathogenic tissues, lactic acid in, 495.
Pathological specimens, 107; from Battey's operation, 459.
Pathology; infantile dentition in, 502; of arterio-capillary fibroid kidney, 538.
Peculiarities of malaria in children, 475.
Pedunculated growth of labium, 494.
Pelvic abscesses; treatment of, 71, 336; simulating uterine fibroid, 537; tumor complicating pregnancy, 595.
Pemphigus; fatal case of, 19; of eyes, 409; acute febrile, 570.
Pennsylvania Hospital; history of, 32; banquet, 61; popularity of, 93.
Penetrating wounds, laparotomy in, 369.
Penis; deformed, 537; retraction of, 762.
Perfection of ophthalmic surgery, 471.
Perforating ulcer of stomach, 408; of foot, 506.
Perforation, occurrence of, 311; of vermiform appendix, 442; of appendix vermiformis, 689.
Pericardial friction murmurs, 163.
Pericarditis; salicylate of sodium in, 314; and pertussis, 504.
Perihepatitis of portal vein, 9.
Perineorraphy, 717.
Perinephritic cysts, 174.
Perineum; ruptured, 9; lacerated, 11; laceration of, 431; lesions of, 665.
Periosteal sarcoma of femur, 335.
Peripheral nerve lesions, arthritis from, 283.
Peritoneal dropsy, 709, 742.
Peritonitis; diffuse, 442; encapsulated pelvic, 685.
Permanganate; of potassa, 568; of potash in carbuncle, 792.
Permanent drainage in ascites, 398.
Pertussis; chloride of gold and sodium in, 120; pleurisy in, 187; and pericarditis, 504.
Perityphlitis, case of, 165, 205; cause of, 471.
Pessimist patient, 191.
Pessaries, use of, 527.
Pharmaceutical preparations, 318.
Pharyngeal, naso-, reflex, 539.
Pharynx, herpes of, 250.
Phenomena, reflex nervous, 375.
Philadelphia delegates, the report of, 758.
Philosophy of drinking largely, 78.
Phimosis in infancy, 401.
Phosphorus, necrosis from use of, 536.
Phthisis to syphilis, relation of, 87; catarrhal treatment of, 147; syphilitic, case of. 147; pulmonalis, 360; laryngeal, pregnancy complicated with, 428; protection from, 507; in mill hands, 671; incipient, 785.
Physical signs of pneumonic consolidation, 175.
Physician's; clinical record, 23; peril of, 253; and pathologists, association of, 319; difficulties of,

414; women, abroad, 574; female, in insane asylums, 749.
Physiological effects of guaranine, 248.
Pichi, 571; Chilian remedy for cystitis, 25.
Pigeon-keeping, diphtheria, 479.
Pigeons, carrier, rapidity of flight, 159.
Pigmentosum atrophoderma, 243.
Pilocarpine in erysipelas, 202; in fish-poisoning, 404; in pneumonia, 410.
Pimples on nose, 445.
Pistol-shot wound of abdomen, 418; of abdomen, laparotomy for, 739.
Placenta prævia, labor complicated by, 197, 203; conception while uterus contained a, 247; double battledoor, 429.
Planting of fruit trees, 413.
Pleurisy in pertussis, 187; with anomalous symptoms, 257; diaphragmatic, 399; with effusion, 441; cause of, 467.
Pleuro pneumonia, to suppress, 287.
Pneumatic cabinet for pulmonary diseases, 227; differentiation, 461; cabinet, application of, 669, 670.
Pneumonia to syphilis, relation of, 87; latent, 119, antipyrin and calomel compared in, 371; pilocarpin in, 410; treatment of, 530; croupous, of lung, 568; croupous and hypostatic, 596; seasonal, prevalence of, 721.
Pneumonic abscess, 110; consolidation, physical signs of, 175.
Pneumothorax, peculiar case of, 599.
Poison in Georgia, 159.
Poisons, antidotes for, 557.
Poisoned by tea, 474.
Poisoning; mushroom, 23; by datura stramonium, 25; by seed of datura stramonium, 241; lead, 97, 412, 439; nitrite acid, 247; from drinking water, 273; by sulphuretted hydrogen, 274; from quinine, 282; pyæmia, or blood-, 292; by chlorate of potassium, 305; by household utensils, 372; fish, pilocarpine in, 404; rhus, 413, 603; rhus, treatment of, 508; by paraffin oil, 534; aconite, 583; by stramoninm, 594; lead, diagnosis of, 761; ivy, treatment of, 762; cocaine, antidote to, 790.
Poisonous effect of oil of sassafras, 345; infection, prevention of, 438; honey, 447.
Policing the high seas, 733.
Polypi, aural, treatment of, 219; nasal, removal of, 464.
Polypus, fibroid of uterus, 777.
Polygonum aviculare, 512.
Popliteal aneurism, 154.
Popular prejudices concerning food, 477.
Portal vein, perihepatitis of, 9.
Porro's operation in Japan, 159.
Port-wine marks, treatment of, 435.
Post-mortem hyperpyrexia, 314.
Post-partum hemorrhage, 745; strychnia in, 249.
Potassa, permanganate of, 568.
Potash. permanganate, in carbuncle, 792.
Potassium, chlorate, poisoning by, 305.
Pott's disease of spine, 769.
Powder, cleaning, for windows, 447.
Practice in Utah, 478; illegal, 533.
Practical value of estimating amount of urea daily, 22.
Practitioners, medical, animals as. 241.
Precautions in removal of urine, 505.
Pregnancy, diagnostic signs of, 74; diagnosis of, 136; vomiting of, 156; bloody urine in, 168; treatment of hemorrhoids in, 223; displaced spleen and, 242; mistaken for cysto-sarcoma, 313; complicated with laryngeal phthisis, 428; emboli in. 437; pelvic tumor complicating, 595; tubal, 657; early diagnosis of, 678; perforation of vermiformis during, 689; vomiting during, 759; extra uterine, 803.
Premature rupture of membranes, 299.
Preparation of terpene, 792.
Presentation, breech, complicated by large scrotum, 346; an unique, 428.
Preventive inoculation by Russian priest, 318.
Prevention of mammary abscess, 153; of myopia in school children, 312; of poisonous infection, 438.
Primitive endocarditis in soldiers, 444.
Probable floating spleen, 360.
Profession in Russia, 351.
Professional etiquette, 351.
Professor Von Bergmann, 31; Verneuil, on surgical ethics, 177; of Anatomy in the Jefferson, 541; Forbes, 598.
Progress of otology, 120.
Prophylactic measure, arterial ligation as, 112; against cold, 475.
Prophylaxis of cancer, 349.
Prolapse of rectum, 432, 443.
Prolapsus uteri, 73.
Prostate, hypertrophy, 412; cocaine in treatment of, 752.
Prostatic catheter, 91.
Prostatitis, desquamative, with hyaline casts, 276.
Protection of streams, 325, 353; from phthisis, 507.
Protracted labor, 626.
Provisional regulations, 59.
Pruritus, 188; vulvæ, operation for, 145; of anus, 540; and coffee, 725; ani, treatment of, 789.
Pseudo-parasite of man, 55.
Psoriasis, 232; galium aparine in, 476.
Psychology, fœtal, 487.
Puberty, early, 316.
Purpura, senile, 298.
Puerperal; sepsis, 40, 424; insanity, 535; fever, 673, 761.
Pulmonalis, phthisis, 360.
Pulmonary; capacity, 218; diseases, treatment of, 227; lesions, terpene in, 434; tuberculosis, inhalations in, 570.
Purification of water, 783.
Pustule, malignant, recovery from, 113.
Pyæmia or blood-poisoning, 292.
Pylorus, excision of, 694.
Pyosalpinx, 362, 458, 714.
Pyonephrosis, 175.
Pyridin, 686.

Quackery and punishment in Holland, 287.
Quarantine inspection, 415.
Quinine; in high altitudes, 93; poisoning from, 282; in typhoid fever, 348; idiosyncrasy, 371; intolerance of, 599.
Quinsy; of rheumatism, 215; as rheumatism, 365; treatment of, 465.
Quintuple labor, case of, 178.

Rabies and snake-bites, 319.
Race, sacrum an index of, 156.
Radical; cure of hydrocele, 409; of inguinal hernia, 617.

Radius, partial dislocation of head of, 244.
Rags, disinfection of, 126, 478.
Railroad accidents, nervous diseases after, 565.
Rash, belladonna, 188.
Raynod's disease? 398.
Recovery; of speech, 27; from malignant pustule, 113; from abortion, 625.
Rectum; stricture of, 296; feeding by, 313; affections of, 403; treating prolapse of, 432; prolapse of, 443; congenital stricture of, 720.
Reflex; vaso-motor neurosis, 370; nervous phenomena, 375; symptoms in nasal affections, 493.
Regulations, provisional, 59.
Regurgitation, mitral, and aortic obstruction, 231.
Remarkable; Italian fecundity, 31; instance of longevity, 158; toleration of foreign body in eye, 304; fecundity, 474.
Remedy; for cystitis, 125; new, in diphtheria, 151; for ozæna, 153; for bee-stings, 413; for chronic diarrhœa, 743.
Removal; of iron from eye, 222; of nasal polypi, 464; of splinter from orbit, 488, 494; of residual urine, 505; of spleen, 628; of lower jaw, 649; of foreign bodies, 697; of ovarian tumor, 780.
Renal; abscess, 411; calculus, 659.
Replacement of tendon, 632.
Reproduction of femur, 538.
Resection; of ribs for tumor of chest-wall, 57; osteo-plastic, 781.
Residual urine, removal of, 505.
Resorcin; in gonorrhœa, 341; in skin diseases, 501.
Respiration, artificial, 622, 663.
Respiratory; organs, meteorological changes on diseases of, 117; croaking of babies, 344; changes in animals, 669.
Resuscitating new-born child, Schultz's method of, 154.
Retention; of broken glass in vagina, 24; cyst of submaxillary gland, 335; of urine, cocaine in, 752.
Retina, cholesterine in, 507.
Retirement of Sir Joseph Hooker and Professor Huxley, 61.
Retraction of penis, 762.
Retroversion of uterus, 289.

Solution, Dover's, 347.
Sounds on hearing, 538.
Sour milk in atonic dyspepsia, 55.
Spain, vaccination service in, 63.
Spasm of sphincter ani, 248; or paralysis? 249.
Spasmodic croup complicating measles, 148; contraction of abdominal muscles, 473.
Special report, progress of otology, 120.
Speech; recovery of, 27; of the eyes, 117.
Spermatic cord, abscess in, 472.
Sphincter; ani, dilatation of, 17; subcutaneous division of, 180; spasm of, 248.
Spina bifida, treatment of, 567.
Spinal; curvature, 570; connection between affections of eye and, 119; tumors, diagnosis of, 552; cord, removal of, 554; cord, cervical, 588; sclerosis and osteo-arthritis, 601; cord, tubercular disease of, 619.
Spine; lateral curvature of, 72; Pott's disease of, 769.
Spleen; rupture of, 264; displaced and pregnancy, 242; probable floating, 360; removal of, 628.
Sponges in ovariotomy, 570.
Sprained joints, 505.
Squint; convergent, operation for, 219; intense, myopia with, 494.
Staining wood, 510.
Stammering; cure for, 95; of urinary organs, 216.
Stannous chloride, disinfectant value of, 447.
State Board of Health, 63.
Staufer's instruments, 318.
Stenosis; mitral, 621; in labor, 696.
Sterility, 170.
Still-birth, artificial respiration in, 663.
Stomach; diagnosis in ulcer of, 80; multiple myoma of, 175; tube, obstinate vomiting cured by, 243; chronic simple ulcers of, 311; sick, treat-

ment of, 346; perforating ulcer of, 408; prognosis of cancer of, 793.
Stomachic vertigo, 203.
Stone, sacculated, in the bladder, 751.
Stones, gall, passage of, 361.
Stramonium, datura, poisoning by, 25, 241, 594.
Strabismus, convergent, treatment of, 314.
Strangulated hernia, operations for, 400.
Stretching, nerves in sciatica, 38, 57, 109.
Stricture; of the ileum, 56; of rectum, 296; of certain gliomata, 586; impermeable, treatment of, 749; electrolysis for, 793.
Strictures, congenital of rectum, 720.
Strychnia in post-partum hemorrhage, 249; hypodermatically, 443.
Strychnine in dipsomania, 727.
Students; Edinburgh, and the academic robes, 191; a word to, 407.
Stunning by electric lamp, 338.
Stump, aneurism occurring in, 466.
Sublimate, corrosive, danger from, 475.
Subcutaneous division of sphincter ani, 180.
Submaxillary gland, retention cyst of, 335.
Substitute for gum senegal, 444.
Succession duties claimed on surgeon's fee, 317.
Sudden; origin of diabetes, 88; fatal cerebral hemorrhage, 257; blindness during labor, 572.
Suggestion on proper alternation of rest, 239.
Suicide by butting head, 633.
Suicides in great cities, 575.
Suit for malpraxis, 579.
Sulphate of thallin, 572; of sodium, 724.
Sulphur in gas, 309, 318.
Sulphuretted hydrogen, poisoning by, 274.
Sunstroke, sequel of, 44.
Super-fœtation, case of, 142.
Supernumerary fingers, 316; mamma, 336; breasts and nipples, 505.
Suppurative nephritis, acute primary, 493.
Supra-pubic operation of lithotomy, 249.
Surgeon's fee, succession duties claimed, 317; to Penna R. R. Co., 607.
Surgery; laryngeal, results of, 48; practical, contributions to, 240; ophthalmic, perfection of, 471; antiseptic, 511.
Surgical ethics, 177; treatment of cysts, 310; affections in insane, 791.
Suture of nerves in recent injuries, 475; catgut, of patella, 600.
Suturing median nerve, 618, 697.
Swallowing, painful and imperfect, treatment of, 56; a caterpillar, symptoms from, 247.
Sweats, night, treatment of, 728.
Symblepharon of lower lid, 649.
Symmetrical synovitis of knee, 435.
Symmetry, imperfect, 790.
Symptom in megrim and epilepsy, 311.
Symptoms from swallowing a caterpillar, 247; anomalous pleurisy with, 257; rare, in hemiplegia, 348; from laceration of cervix uteri, 455; reflex, in nasal affections, 493; of neurasthenia, 521; of chronic tetanus, 559; of stramonium poisoning, 594.
Synovitis, symmetrical, of knee, 435.
Syphilides, treatment of, 632.
Syphilis, diphtheria complicating, 79; relation of phthisis to, 87; micro-organism of, 116; non-venereal, 223; limitation, period of contagious, 223; abortive treatment of, 281; bichloride of mercury and urea for, 345; hereditary, 417, 435; transmittent of, 539; cerebral, 561; cerebral, treatment of, 632.
Syphilitic iritis, 40; ulceration of vocal cords, 56; phthisis, case of, 147; hemiplegia, 216; disease, 588.
Syringe for travelers, 189.

Tænia, treatment of, 377.
Tax on burials, 318.
Tapeworms in one person, 24.
Tea, poisoned by, 474.
Technic of thermometers, 87.
Teeth, transplantation of, 601; alum gargles on, 697.
Temperature on life of the fœtus, influence of, 94; curve, inversion of, 602.
Tendon, replacement of, 632.
Terebene in winter-cough, 499.
Tertiary syphilis, treatment of, 223.
Terpene in chronic bronchitis, 147; in pulmonary lesions, 434; preparation of, 791.
Test for human milk, 119; for sugar in urine, 497; for cocaine, 601.
Testimony in insanity cases, 29; expert, 703.
Testicle, tumor of, 75; partially descended, 335; absence of, 474.
Testes, tubercular, 176.
Tetanus, 193, 225; chronic, symptoms of, 559.
Thallin, 183, 503; sulphate of, 572.
Theine, 26.
Therapeutic; use of digestive ferments, 562; value of mineral springs, 670.
Therapeutics; bacterio, attempt at, 373; metallo, 725; of syphilis, 792.
Thermic fever, cases of, 49.
Thermo-cautery, a new, 618.
Thermometers; technic of, 87; clinical, 602.
Thigh, sarcoma of, 650.
Thoracic organs, massage of, 154.
Thrombosis of portal vein, 9, 632.
Thrush, treatment of, 184.
Thumb; dislocation of ungual phalanx of, 186; joints, dystrophy of, 443.
Tibia; caries of, 329; comminuted fracture of head of, 343; necrosis of, 769.
Tipple, the ladies', 158.
Tissues, pathogenic, lactic acid in, 495.
Tobacco, use of, 90.
Toe nail, inverted, 297, 476.
Tolu varnish in diphtheria, 185.
Tonic, a new heart, 155.
Tongue; abnormal mobility of, 159, 211; epithelioma of, 449.
Tonsillitis; cases of, 44; acute, treatment of, 411.
Tooth; curious position of, 444; growing in nose, 472.
Trachea, diverticula of, 685.
Tracheotomy, 73, 260; apparent death after, 663.
Training, manual, in United States, 447.
Transfusion, suggestions for, 188.
Transplantation; in recent wounds, 57; of eyeball, 221, 472; of teeth, 601.
Travelers, useful syringe for, 189.
Traumatic; epilepsy, trephining in, 432; atresia of cervix uteri, 522; inguinal aneurism, 535, 690; nephrosis, 629.
Treatment; of nasal polypus, 16; of hysteria, 29; of painful swallowing, 56; of sciatica, 57, 729; of pelvic abscess, 71; of albuminuria, 83; of Blackwater fever, 88; of habitual constipation, 113; of lienteric diarrhœa in children, 119; of

vomiting, 129, 161 ; of catarrhal phthisis, 147 ; of Colles' fracture by new method, 152; of intertrigo, 184 ; of thrush, 184 ; of carbuncle, 188 ; of non-union fractures, 219; of aural polypi, 219; of hydrocele, 221, 475 ; of varicocele, 221; of diphtheria, 221, 471 ; of hemorrhoids in pregnancy, 223 ; of tertiary syphilis, 223 ; of bronchial and pulmonary diseases, 227 ; of labor, 270 ; abortive, of syphilis, 281 ; of membranous croup, 283 ; of cysts, 310 ; of lithæmia, 313 ; of tuberculosis of lungs, 314 ; of convergent strabismus, 314; of pelvic abscesses in women, 336 ; of gonorrhœa, germicidally, 337 ; of enuresis, 346 ; of sick stomach after ether, 346 ; of penetrating wounds, 369 ; of tænia, 377 ; of bronchitis, 377 ; of intestinal obstruction, 378, 663 ; of cholera infantum, 378 ; of empyema, 379 ; of endocarditis, 410 ; of acute tonsillitis, 411 ; of skin diseases, 419 ; of prolapse of rectum, 432, 443 ; of port-wine marks, 435 ; of morphine habit with cocaine, 439 ; antipyretic, 462 ; of chronic ulcers, 463 ; of quinsy, 465 ; of catarrhal icterus, 470 ; of winter cough, 499 ; of distended gall-bladder, 506 ; of neuralgia, 508 ; of rhus poisoning, 508 ; of pneumonia, 530 ; of neurasthenia, 550 ; for radical cure of hernia, 558 ; of spina-bifida, 567 ; of fractured clavicle, 567 ; of malpraxis, 579 ; of crusting syphilides, 632 ; of cerebral syphilis, 632 ; of uterine cancer, 695 ; of chronic nasal catarrh, 727; of night-sweats, 728 ; of impermeable stricture, 749 ; of vomiting during pregnancy, 759 ; of hernia, 760 ; of acute rheumatism, 760; for masturbation, 760 ; of ivy poisoning, 762 ; of inebriates, 771 ; of pruritus ani, 789 ; of club-foot, 790 ; of dysentery, 791.
Tremor, lead, 537.

W. H. SCHIEFFELIN & CO'S.,

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1431- 1499

THE HIGHEST AWARD.

THE GOLD MEDAL,

HAS BEEN GRANTED TO

MELLIN'S FOOD

FOR INFANTS AND INVALIDS,

At the World's Exposition, New Orleans, 1885.

A Sample of MELLIN'S FOOD, sufficient for trial, will be sent free to any Physician desiring it.

THE

MEDICAL AND SURGICAL REPORTER.

No. 1505.] PHILADELPHIA, JANUARY 2, 1886. [Vol. LIV.—No. 1.

Original Department.

Clinical Lecture.

BY WALTER HAY, M. D., LL. D.,

Of Chicago,

Professor of Nervous and Mental Diseases and of Mental Jurisprudence.

[Reported by William Whitford.]

NEURITIS.

This patient is 49 years of age, and from the nature of his occupation not exposed to atmospheric conditions, but pursues his business in a uniform temperature. Two weeks ago, we are informed, he went to bed, laid on the right side, and awoke in the morning with severe pain in the right arm, which has been continuous. It is, as you notice, aggravated by linear pressure. He winces sharply when I press upon the painful spot.

Now this condition may be the result of proliferation of connective tissue cells from the blood-vessels, compression of nerve fibres and sensory tracts. Had we seen the case within a few hours after its inception, I should have administered quinine internally. However, we will prescribe him the following:

℞.	Iodine,	1 gram.
	Iodide of potass.,	5 grams.
	Water,	25 grams.

Sig.—Take ten drops in a glass of water every six hours.

I would suggest in addition the application of the galvanic current, which will expedite things very materially. I have a case under treatment almost identical with this. The patient has yielded slightly to galvanism after having persisted for nearly a year.

HEMICHOREA.

Here we have an example of probable retention in the blood of exerementitious matter—uric acid—under the combined influence of dampness and cold. The child is 11 years old, and very delicate. There is pain together with hyperæsthesia about the right shoulder-joint, and the integument surrounding the joint. Observe the coincidence of the pain and hyperæsthesia, and remember that, under certain conditions, we have pain without hyperæsthesia. For example, in neuralgia we rarely have hyperæsthesia; we have pain accompanied with hyperæsthesia, but the hyperæsthesia is of a linear character, it is not diffused over the surface.

We can get but little information regarding the condition of the urine in this case. We have no history of any change in its color, nor of contour of the tissues about the joints, such as redness and swelling, which might readily exist to some extent. The occurrence of coördinate spasm involving one-half of the body, and at times the entire muscular apparatus of that half, indicates clearly the nature of the original malady, and usually supplies the evidence wanting in the history of such cases.

There is a sub-acute rheumatic inflammation about the joints—a poisoning of the motor ganglion cells in the brain, with increased irritability and development of coordinate spasm.

The conditions of this case being almost identical with those of the case we had before us some four weeks ago, I shall direct the same treatment, namely:

℞. Sodium salicylate, 15 grams.
Water, 60 grams.
Sig.—Take a teaspoonful three times a day.

Another feature in connection with this case is that there are frequent attacks of suppurating tonsillitis, and just exactly what relation that bears to the hemichorea cannot be defined very clearly. In cases of blood-poisoning arising from defective elimination of excrementitious matters, I have for a number of years refrained from administering narcotics, for the simple reason that nearly all of them tend to diminish glandular activity, arrest elimination, and retard the depurating process of the blood. I always endeavor to remove the irritating agent from the blood, and, if possible, secure a tranquil condition of the brain. I find this mode of procedure more prompt and satisfactory.

NEURALGIA.

Our next patient is a typical case of neuralgia. She has had no chill; no fever. We have the negative evidence, which is characteristic of it, that is, absence of adequate constitutional disturbance. There is no history of pain, either rheumatic, neuralgic, or otherwise. I might say, it is a pure, uncomplicated case of neuralgia, without a taint of any sort.

I am very glad to exhibit this case, because it presents the characteristics, both positive and negative, in the restriction of the body, its constant recurrence, appearance and disappearance, its lancinating and severe character. We have also the negative evidence of the absence of any corresponding constitutional disturbance. This woman has never been sick, and she only contracts this trouble after a hard day's work. During the day she is exposed to cold and dampness, with additional fatigue at night. With nerve-force reduced, she is in a condition of instability (the correlative of debility) favorable for the operation of such depressing and irritating influences.

You will perceive, also, that the least appreciable pressure causes pain. She tells us that she cannot touch her head because it is so sore, and, at the same time, it makes it feel easy, which enables us to distinguish the condition of the neuralgic nerve itself from those of the sensory nerves contiguous. The neuralgia is associated with contiguous hyperæsthesia, but they are distinct from each other. The hyperæsthesia is revealed at a slight touch of the side of the head, while the neuralgia is controlled by firm pressure upon the painful nerve. This is very frequently the case. Patient will actually complain of the touch of the bed-clothes, and the slightest pressure upon the tenderly-affected part will give relief.

To afford relief and, if possible, cure the case, I recommend the following: Two parts of chloroform, two of olive oil, twenty-five cubic centimetres of the tincture of aconite, and fifty of kerosene oil, to be rubbed on the head, covered with a cotton bandage. Mark this distinctly, because it might be mistaken for some remedy taken internally, and it would be a dangerous dose for any one. It prevents a too rapid evaporation of the chloroform, and at the same time protects the painful parts; it prevents the irritable nerves from atmospheric changes, and a recurrence of the attack. Also make a solution of strychnia $\frac{1}{20}$ grain to three ounces of water, and add to it a little acetic acid, the acetic acid being used to complete the solution of strychnia. Sig.—Take two tablespoonfuls three times a day.

COMMUNICATIONS.

SOME OBSTETRICAL HERESIES.*

BY DAN'L MILLIKIN, M. D.,
Of Hamilton, Ohio,
Lecturer on Medical Jurisprudence and Hygiene, Miami Medical College, Cincinnati.

If I hold to any heretical obstetric

*Read before the Cincinnati Medical Society, December 15, 1885.

opinions, it is with regard to the constricted parts and the means of dilatation.

Now, first, as to the upper constriction at the os uteri. How shall it be safely and quickly dilated? The force of traditional doctrine is such as to breed in us a great reverence for the membranes which enclose the child and the fluid about it. We are taught that the hydraulic pressure exerted by the enclosed amniotic fluid is equal in all directions, and it is therefore the best possible dilator for the uterine mouth. A physicist might be inclined to inquire why the pressure is needed in all directions, since, to accomplish dilatation, there is only needed pressure in that plane in which the os uteri lies.

One with a theoretical knowledge of labor, knowing the position of the uterus at full term, would be inclined to say that the amniotic membranes, when they begin to pout forth from the os uteri, will expend their force chiefly on the mother's sacrum, and that the direct thrust of the membranes does not tend to open the os at all. Only indirectly—only after the bag of waters is actually engaged in the mouth of the uterus—does the lateral pressure exert any dilating influence.

But even when the bag of waters, seeking the direction of least resistance, has crept through the os and into the vagina, its dilating power does not seem to be great. I fully believe that most practitioners, like myself, lose all patience at this stage of the game, rupture the membranes, and terminate the labor without the help of the bag of waters; but I recall one case, though I have seen others similar, in which I found the bag pressing on the perineum, and, on examination, I found only a small os. When the waters were evacuated, this thick and firm os was exposed to the tension of my fingers and the direct pressure of the child's head, and quickly softened and stretched to the last degree. I learned from this case how perfectly inefficient this bag of waters was to accomplish any efficient stretching of the os. I learned that it was at least possible for a great amount of amniotic water, enclosed within a great amount of membranes, to be forced through a very small and distensible os, and yet cause no great amount of dilatation, when subsequent manipulation proved it to be not very hard to dilate.

The truth is, that the membranes lack the strength to make them efficient dilators. If they are nature's own dilators, then nature must be prejudiced in favor of a very rotten piece of apparatus. No mechanician—no obstetrician—would for a moment accept a set of dilators made of such flimsy stuff.

Then comes the question as to whether, the membranes being intact, it may not be better that the child should receive the unavoidable pressure of the uterus equally transmitted by hydraulic pressure on every part of its surface. It is claimed that a child may be injuriously compressed by the uterus, but who ever saw a case reported?

Aside from these questions of blood-pressure, we are told by all the traditions that it is not proper to rupture the membranes early, because the child's presenting part is liable to be thrust against the maternal bones, and so be bruised. Now, can any teacher tell us how the child's presenting part can be expelled without being rudely thrust against the mother's pelvic bones? In the first place, in many cases, the presenting part is actually forced into the superior strait, and not very gently. Then, at the inferior strait, the child's head is absolutely racked out of shape, or, as the books euphemistically say, it is "moulded," and it is oftentimes still further distorted. And, last of all, in passing through a tough, resisting perineum, it often meets with the severest constriction, as from a firm elastic band slipped down from the occiput to the chin. All of this being inevitable in a first labor of a plump woman with a moderately large pelvis, and much of it being inevitable in all labors, what folly for us to be timid or squeamish about the lesser degree of compression against the bones at the brim of the pelvis in the earliest stage of labor! Granting that, by a careful saving of the membranes, we can, without otherwise impeding labor, save the child from this lesser degree of compression at the brim, what's the use of it?

The more I turn this matter over, the

more I become convinced that the membranes have no relation to normal labor whatever. Their function has been performed when labor has begun. They maintained the water-bath during the feeble, earlier existence of the child, but when labor is at hand, the hour has come when the child must surrender its water-bath. It is thenceforth to come against harder structures, not alone during the processes of parturition, but for threescore and ten years.

It follows that, if the attendant is certain that labor has actually begun, and that the presentation of the child is a natural one, so that no turning operation will be needed, he had better evacuate the waters at once. In coming to a conclusion as to whether labor has actually begun, I would, of course regard the state of the cervix and os. There should be no cervix appreciable, for, so long as it remains, there must be some small element of doubt as to whether labor has actually begun, notwithstanding all that we may be able to learn of the duration of pregnancy by other means. As to the os, I would not ordinarily rupture the membranes unless its margins were somewhat soft and distensible; not because I believed that the bag of waters was needed to dilate its margins, but because I would doubt whether labor had actually begun until there was a certain degree of physiological softening.

With these provisos—labor actually begun, no turning operation needed, the cervix inappreciable, the margins of the os becoming soft—the sooner the membranes are ruptured the better.

And why? I might answer this question by the formula which Fortenelle declared had produced more wisdom than any other, *Why not?* The membranes are fœtal structures; the fœtus is about to become a child; a child needs no membranes.

By evacuating the uterus we shorten its fibres, and thus stimulate powerful contractions.

I offer no sort of excuses for advocating an expedient which will abbreviate labor. Other things being equal, a short labor is a good labor. It is better for a woman to have one hundred sharp pains than two hundred; it is better for her to have fifty than one hundred; and the most beautiful labors I have witnessed in four hundred have been those with only fifteen or twenty hard pains.

It cannot be conceived that women of refinement and luxury have the endurance of women who lived the lives of peasants or of pioneers. Nor do I think that the women of this country, which is fast becoming an old country, have the patience that belonged to their mothers or grandmothers. They are absolutely fretted to death by a long labor in many cases, and the accoucheur should give them a short labor if he can.

Then it is not to be believed that the present generation of women can endure pain as did the women of the past. For all child-bearing women of the present time have been born since the skillful use of opiates, of chloroform, of chloral, of ether, and of the hypodermic syringe, have been common; and now comes the hydrochlorate of cocaine to be freely applied in domestic practice to all little cuts and hurts, so that the ministry of pain, educating men and women to endure pain, is almost at an end. This ability of endurance is likely to be still further lowered in the next generation.

After a careful review of my obstetric cases, I can deliberately say that the parturient canal is as well lubricated when there are no waters as when there are waters oozing during the whole period of expulsion. The vagina is fully lubricated during the ordinary sexual orgasm, and on short notice; the same vaginal and uterine glands seldom fail us in labor.

Returning to the proper mode of dilatation of the os uteri, let me appeal to the practice of all obstetricians when they wish to accomplish the dilatation from below, in case of induced labor at or before term. They do not in any case use anything to be compared with the bag of waters. They use the dilators that act like glove-stretchers. Then they use the finger. Possibly, at some stage of the game, they use tents. After the finger they use two fingers. Then they use more fingers, until they have all the dilatation that they need. The rubber dilators

are in no wise comparable to the bag of waters.

The application of the narrow forceps to the head of the child is one of the very best expedients of modern obstetrics.

And now, sir, suffer me a few words as regarding the dilatation of the lower end of the parturient canal. The traditions of the fathers tell us nothing of the value of the membranes in dilating this portion of the canal. The reason is perfectly obvious. So frail are the membranes, that it is not the lot of many practitioners of medicine to have ever seen them projected so far. If of use at the upper end of the canal, they ought to be of use also at the lower; and nature is guilty of a serious blunder in not having them made strong enough to endure until they could dilate the tough sphincter structure of the vaginal opening.

The traditions say nothing about the perineal structures until the head has reached them. Then, when the head of the child has borne heavily upon these structures, a most astonishing performance is resorted to and recommended to you and me. This manœuver is called the support of the perineum.

Let us clearly bear in mind one of the first principles of obstetrics. We cannot pass a head measuring thirteen inches through a hole measuring one whit less than thirteen inches. The perineum must stretch to the full size of the head, whatever it be, unless we deliver it through the rectum. Nothing can save it from such stretching, though I do firmly believe that there are many men who, by faithfully pressing upon the poor woman's bottom for a season, imagine that they have saved the perineum from a certain amount of dilatation that would have been inevitable otherwise.

We may lay a napkin over the hand and support the perineum in the most approved manner; but by that act, through a circuitous route, we are really goading the uterus on to expel the child, and in spite of our protestations and commands, the woman will co-operate. The man who thinks he can retard the expulsion of a child by pressing against its head through the perineum is, I am fully convinced, deceived. He is like one pressing the button to stop the ringing of an electric bell; he is tugging at the throttle of an engine to check its speed; he tries to flog a runaway horse into good behavior.

Not so with the obstetrician who thinks that by pressure he can do something to alter the physiological state of the perineal structures, and fit them for the enormous dilatation to which they must presently submit, as the head passes into the world. But when we find him at his work, we may fitly ask him why he does violence to the perineum from the outside. Seeing that it must presently stretch, why not begin to stretch from the inside? It has been my practice for about two hundred labors to drag down on the perineum with two fingers, and sometimes with three, just before the descending head has begun to impinge upon it, and I have friends and neighbors who have resorted to the same procedure during the management of at least two hundred labors more. We are well assured that, if the labor does not approach the precipitate character—that is, if there are ten to twenty pains during which we may make traction in advance of the head—there is, without any additional suffering to the woman, a very decided alteration in the perineal structure, and in many cases we find it fully prepared for the passage of the head before the head is perfectly free from the pelvis. This may and must be done with reasonable force and synchronously with the expulsive efforts of the woman, so that no addition is made to her sufferings. Indeed, when I have cautiously resorted to this tension, I have often seen my patient brighten up and say, "Now I feel like I was working for something!"

But you may ask, "What's to be done when the head is absolutely distending the perineum?" I can only say that if at the supreme moment you have any little bit or scrap of a prayer about you, you may say it, but you can't help the poor woman by tinkering with her. The perineum must stretch until the vulvar circumference is precisely as great as the circumference of the child's

head. The time for stretching has come, and you can't avert it.

Unless pressure on the outside of the perineum can in some mysterious way save the perineum from stretching, it is, in my humble opinion, a superfluous annoyance to a poor creature who ought not to be annoyed.

Let us hear the conclusion of the whole matter: *The fingers and the presenting part of the child form the only efficient dilators of the constricted parts of the parturient canal.*

UNILATERAL HALLUCINATIONS.*

BY WILLIAM A. HAMMOND, M. D.,

Of New York.

The fact that hallucinations of sight and of hearing might be unilateral, that is, discerned by one visual or auditory centre only, had long been known, though it had not, even at this day, attracted the degree of attention which Dr. Hammond thought it deserved. Several authors had considered the matter from a more or less philosophical standpoint, and had brought forward interesting cases in support of their views. The first reference to the fact that hallucinations might be one-sided which had come under his notice was made by Calmet, it being a case of hallucination coming from the left ear. Baillarger cited two cases of hallucinations of hearing occurring in but one ear; other writers who had contributed to the subject, and cited by Dr. Hammond, were, Michia, Schroeder Von der Kolk, Alexander Robertson, E. Regis, Dumont Pallier; erroneous impressions, of different character, occurring on either side, had received attention at the Medical Congress at Rouen in 1883.

Dr. Hammond then gave the histories of several cases of unilateral hallucinations which had come under his own observation. The first was that of a gentleman in good general health, who contracted the illusion that the ticking of a clock on the mantelpiece consisted of articulate words, which, after a time seemed to sound like human speech, and appeared to give commands, such as not to eat of soup, not to drink wine, etc. It was learned that these illusions came only through the left ear, and never through the right; but hearing in other respects was not the least impaired in either ear. The patient did not allow himself to be deceived into the idea of accepting these commands as realities; yet he was influenced by them in his actions. This case and the one next mentioned were referred to in Dr. Hammond's work on insanity.

Case 2. A young lady, of good mental development, but of delicate physical organization, was for several months almost constantly troubled with apparitions of various kinds of faces. A few weeks before they first appeared she had looked at engravings of Greek and Roman masks, which had made a strong impression upon her. If she closed either eye, about half of the faces would disappear, and if she closed both eyes all would disappear, but would return again in a little while, although less distinctly. By imitating the experiment of Sir David Brewster, pressing on the outside of the globe of either eye so as to produce temporary strabismus, the patient could make any face appear double which had been visible for several minutes. There was no impairment of vision of any other kind, and no abnormal ophthalmoscopical appearances. The peculiar features of this case were, that the hallucinating images were divided between the two eyes, part being seen in the one and part in the other, showing therefore the distinctness and divisibility of the action of the two visual centres, and the fact that the stimulus of a strong light was necessary in order that they should be developed.

Case 3. A young man received a blow just above the left ear. A few weeks subsequently, while engaged as a salesman, he saw a large black cat sitting on the floor immediately before him. He had no doubt of the reality of the occurrence, until he walked toward the animal, when it receded as far as it was when he first saw it. After this the cat seemed to follow him wherever he went, but his sense of touch was never deceived. The image was largest and most distinct in the evening, and during the paroxysms of pain at the seat of the injury

* Abstract of a paper read before the New York Neurological Society.

on the head, which returned several times a day. He discovered on shutting his eyes alternately, that the vision occurred only on the side corresponding to the injury. There were no abnormal ophthalmoscopical appearances nor impairment of vision in other respects than mentioned. That there was serious brain lesion, involving probably the left optic thalamus, Dr. Hammond said he had no doubt. He had also been of opinion that there had been fracture of the inner table of the skull at the point at which the blow had been received, and he proposed trephining, which was not consented to.

Case 4. A lady, about fifty years of age, became subject to most malignant persecutions through anonymous letters, the sender of which she did not know. Thinking of who the person could be that sent the anonymous letters, she happened to look out of the bay-window and saw a man and woman standing in the opening. For a moment she did not doubt the reality of the appearance, but when she arose, they gradually faded from view. Afterward they reappeared several times in the month, and finally ceased to appear altogether. The interesting feature of the case was that the man was always seen with the right eye and the woman with the left; if she closed the right eye she saw only the woman, but if she closed the left eye she would see only the man. The vision could be brought on by lying down with the head low. Dr. Hammond thought nothing could be more confirmatory of the idea of the independent action of the two visual centres than such hallucinations; indeed, he thought they were strong evidence of the duality of the brain. None of the cases which Dr. Hammond had cited went to support the view that unilateral hallucinations were due to disease or derangement of the organ of special sense involved. Indeed, it was difficult to conceive what connection could exist between disease of the eyes or ears and a hallucination existing in the corresponding side; for if such disease caused a unilateral hallucination, we should expect bilateral hallucinations to be the result of disease of both eyes and ears. Dr. Hammond thought hallucinations were produced by disease or disorder of the central organ of perception, probably of the optic thalamus, and that such erroneous sensorial impressions, when limited to one side, were evidence that the visual, auditory, or other sensorial centre of the corresponding side was the starting point.

VAGINAL AND VULVAR ENTEROCELE.*

BY T. GAILLARD THOMAS, M. D.,
Of New York.

For practical purposes herniæ into the vagina and vulva could be divided into the following five varieties: 1, Cystocele; 2, Rectocele; 3, Vaginal Enterocele; 4, Pudendal Enterocele; 5, Perinaal Enterocele. There were other exceptional forms. Hernia of the bladder and of the anterior wall of the rectum were merely mentioned. The author confined his remarks chiefly to descent of the intestine through the pelvic roof, with protrusion into the labium major, vagina or perineum. While the condition was very generally ignored in systematic works on gynæcology, it was one of great importance, because, being rare, it was liable not to be correctly diagnosticated and to lead to serious results from mistreatment. A few authors, however, had contributed valuable information regarding the subject. Vaginal enterocele had been graphically described by John Hunter as early as 1804. One of the possible dangers in vaginal enterocele was illustrated in a case which Dr. Thomas saw in consultation with two other physicians, one of whom, in order to convince himself of the exact condition present, insisted upon inserting his whole hand into the vaginal canal. In doing this he ruptured the vaginal wall of the hernia, and the gut escaped. Dr. Thomas sewed up the rent, and the patient came near losing her life from an attack of acute peritonitis, and the physician was sued for malpractice. There had been another case in which a similar accident arose from the use of tents. The rent was closed with silver wire, and the patient recovered.

* Abstract of paper read before the New York Academy of Medicine.

Dr. Thomas related a remarkable case of extreme vaginal hernia, which illustrated some new and interesting features. The patient was thirty-nine years of age. About six years ago she noticed a tumor in the right vulva, and she began to suffer from frequent micturition, pains in the back, nervousness, etc. During the past six years the tumor had steadily increased in size until it had come down to the middle of the thigh on the right side. The patient was greatly emaciated, suffered severely from the symptoms enumerated, and was willing to undergo any treatment for relief. If she reduced the tumor, the interference with the functions of the bladder and rectum was such that she would have to voluntarily force it down again. Dr. Thomas found a pinkish-colored tumor, extending to the middle of the thigh, with all the appearances of a huge cystocele, but which it seemed evident, on further examination, was an enterocele. It was utterly impossible to retain it in the pelvic cavity, because of its large size and because of its interference with the functions of the bladder and rectum. As relief was urgently demanded, he proposed the following operation: To do laparotomy, have an assistant keep the hernial sac well up with his hand in the vagina; empty the sac of its contents, seize it at its most dependent part, drag it up into the abdominal wound, fasten it there by suture, sustaining the heavy sac by means of two knitting-needles passed through and lying flat on the abdominal integument. Drs. Bozeman and Emmet saw the patient, confirmed the diagnosis, and endorsed the proposed operation. As the operation was proceeded with, Dr. Thomas was surprised to find apparently a soft fibrous tumor pushed up from below on a level with the symphysis pubis, very movable, covered by peritoneum, disconnected with the uterus and bladder. Being entirely at a loss as to its nature, he decided to remove it. The peritoneal covering was split, the tumor removed, the sac drained by a glass tube; the sac was fastened into the abdominal wound as had been proposed. The operation was done more than five years ago, and the patient had made a good recovery; there had been no return of the hernia.

His explanation was that this very movable tumor had originally pushed the vagina before it by entering the pelvic cavity behind the broad ligament on the right side, and, the intestines pressing down upon it, the tumor and the gut made up the contents of the sac.

The question then arose, what was the nature of the tumor? The microscopical examination was made by Dr. H. C. Coe, who reported as follows: The measurements are, 22 by 15 centimetres; average thickness, 1½ to 2 centimetres. The growth is covered in some places by peritoneum, in places being torn, marking adhesions. The interior is bloodless. On section there are no signs of a cyst, nothing but softened, œdematous fibrous tissus, easily separated by the fingers, so as to form pseudo-cavities; there are no true cavities. Varying color at different points. Microscopically, the growth consists of ordinary fibro-muscular tissue, similar to that found in uterine fibro-myoma. Dr. Coe drew the following inferences: 1. This is not an organ, that is, the bladder. 2. It is not an ovarian cyst. 3. It is not composed, at least to any great extent, of inflammatory tissue. What is it? I submit two theories, both of which are merely theories, namely: 1. The growth is a local hypertrophy of pelvic connective tissue. 2. It is a sub-peritoneal uterine fibroid which has become thoroughly œdematous. Dr. Coe gave his reasons for inclining toward the former view. Dr. Thomas was also disposed to accept the view that the tumor belonged to one of the rare and curious classes of pelvic growths which have been described by some European writers.

Regarding the treatment of the class of herniæ under consideration, only one form, namely, inguinal pudendocele, offered relief from mechanical appliances. Should strangulation occur in any of the forms, the indications would be the same as in ordinary inguinal hernia, namely, to cut the constricting band by means of a probe-pointed bistoury. Dr. Thomas said that if another case of large vaginal hernia should present

itself, he should feel inclined to adopt the procedure proposed and partially carried out in the case related, namely, to perform laparotomy, drag up the sac, and fasten it into the abdominal wound.

Ruptured Perineum.

I want to show you, gentlemen, a case that I operated upon three weeks ago; one week ago I removed the stitches, and I have union everywhere, with a thick, strong perineum, save one little point, which I will touch with the solid caustic to hasten union. All operations on the perineum are very successful, save where the sphincter is torn, and then there is a certain percentage of failures, though even under these circumstances it is very successful. This womb, that formerly measured five inches, is now a trifle over two and a half.

Fibroid of the Uterus.

This woman, 27 years old, is married, and has had two children, the last labor being instrumental, and she has never been well since. She complains of vertical and sacral pain, leucorrhœa and difficult menses. We would suppose either that there had been a laceration and sub-involution, or the latter alone, with probably an intra-uterine growth. The uterus, being a constructive organ, is very vascular, and emotions acting through the ovaries will invite still more blood to it; thus, when you remove the ovaries you cure fibroids. This nutritive energy has, no doubt, in this case, caused soft warts to form within the uterus—sort of fungus vegetations. This is a disease of old maids and of women who have ceased to bear children. This womb measures four inches, and there has been a tear of the neck. This is very large unless there is a fibroid; it is very unusual to find a womb so large unless there is a polypus inside or a fibroid in the wall. She is fat, and this makes it difficult to feel a fibroid by external manipulation. I will scrape or curette these vegetations. There are two curettes, one sharp and one dull; I prefer the sharp instrument, as being more radical, but it is also more dangerous, and you must handle it very gently. I do not find as many vegetations as I had expected, and I am strongly inclined to think there is a fibroid here. In such cases the hemorrhage is sometimes maintained by the vegetations, and when we scrape them away it ceases; but remember that a uterus with a fibroid is a very vulnerable organ, and must be handled gingerly. After the vegetations are removed I apply iodine to make the parts aseptic, and to destroy those which have been bruised but not removed. If the cervical canal is not large enough to admit the curette, I dilate it. I will give this woman ten minims of the fluid extract of ergot before each meal, and ten grains of chloride of ammonium thrice daily. The combination is a good one for bleeding wombs from any cause, save when there is cancer.

Service of Dr. William Pepper.

Perihepatitis and Thrombosis of the Portal Vein, with Ascites.

This man is a laborer, 36 years old, and exceedingly intemperate. He always takes at least three large drinks of raw spirits, usually on an empty stomach, daily, and frequently goes on protracted sprees. Such has been his habit for twenty years. We gather an uncertain history concerning syphilis; he has had gonorrhœa and some venereal sores, but they were apparently non-infecting, at least, he has never had secondary manifestations. His family history is bad; his father, like himself, was a drunkard, and died of delirium tremens, and one brother has died of phthisis. His own constitution must have been very strong, for in spite of his self abuse, he has been in the main strong and healthy. Two years ago he had pneumonia, and at eighteen years of age had pleurisy. In the beginning of December he started on one of his protracted sprees, and soon began to feel chilly and dull, but had no distinct chill. The next day he noticed that it required less whisky than usual to affect him. On the fourth of December he became very drunk, and while so, fell, striking his belly. He was momentarily unconscious, and began at once to experience most excruciating lancinating pains in his belly, which were aggravated by movements, but not by the movements of respiration; there was no cough; his abdomen was sore all over, and for three days he passed no urine; the catheter, however, brought away a small quantity of dark brown urine that contained no blood. His stomach was irritable, and the abdominal pain was very severe for three or four days, passing off and leaving a feeling of soreness. A week later his abdomen was still sensitive

and he had much hiccough. The belly now began to swell, and there was pain and oppression in the chest. His urine was more free. He entered the hospital on the 14th, when he seemed to be fairly well nourished, his face a little drawn and haggard as we see in peritoneal troubles, the breathing hurried, tongue coated, costive, belly enormously distended, and marked fluctuation. The veins in the sides of the abdomen were distended, and along the margins of the ribs the capillaries were dilated. As he turned in bed, the fluid gravitated, changing the level of dullness, and there was a little liquid in the left pleural sac. The pulse was dicrotic and moderately full, but there was a peculiar murmur (possibly a blood murmur) over the point of the heart. The urine was scanty and contained albumen; there was no jaundice nor general œdema. Here was wonderfully rapid ascites, brought on by an injury, in an intemperate man. There could be no doubt of the presence of ascites, because of the uniform distribution of the enlargement, the marked fluctuation, and the change, with change of position, of the level of dullness. The next question was as to the cause. There might be two causes. It might have come from the liver, for any cause of portal obstruction (most usually cirrhosis) would produce it. In this case, we had a right to suspect cirrhosis, from the man's habit, for the consumption of raw spirits on an empty stomach is the most prolific cause; but it came on so abruptly, which is not the rule with cirrhotic ascites—it appeared, you see, between the receipt of the injury on the fourth, and the eleventh. It was necessary to tap him, and we drew off more than eight pints.

Again, apart from the dropsy, the only evidence of cirrhosis was the zone of distended capillaries about the base of the chest, which demonstrated some obstruction to the abdominal circulation; but there were no hemorrhoids, nor marked gastric disorder, as is common in cirrhosis. The liver is sometimes enlarged throughout the whole course of cirrhosis, but usually it is contracted in the more advanced stages. Since he was tapped, we can make out the liver, which is about normal in size; this does not, however, disprove cirrhosis, though it does make me unwilling to accept it as the sole cause of the ascites. If there exists a certain degree of cirrhosis, a little more acute obstruction would cause ascites. Simple thrombosis or inflammation of the portal vein, leading to secondary thrombosis, would cause it; but such cases are very rare. The symptoms are acute pain, tenderness over the fissure of the liver, moderate febrile disturbance, and in inflammatory thrombosis a septic process, maybe pyemia, distended belly, and ascites. Such an obstruction may be complete and permanent, causing recurring ascites, the portal vein becoming obliterated, forming a fibrous cord, or it may not be absolute, or it may be subsequently absorbed, when the dropsy will subside, or, at least, will not recur so rapidly. The causes of thrombosis are often traumatic, as a blow, a heavy fall, pressure from certain occupations, where the abdomen is pressed against the side of a table; this case suggests that an injury to the portal vein has been the cause. You must remember that peritonitis, in all its forms, is accompanied by effusion; but in this case we cannot entertain the idea of a general peritonitis; his condition has been too good. But in some cases you will find it necessary to resort to the crucial test, and to make a chemical and microscopical examination of the ascitic fluid. We did that here, and found a brown liquid, containing a small amount of albumen, with a trace of sugar, urea, chlorides, and some indican; no shreds of lymph, some red blood globules, and some pus corpuscles. In ascitic fluid from peritonitis there is usually a great deal of albumen, urea, and chlorides; the fluid is clear, transparent, and you will usually find a few cells from the peritoneal surface, and possibly a few leucocytes. Indican has no clinical significance, so far as we know as yet, though I am making some observations with reference to it that will determine whether it has any value or not. If there were general peritonitis, the fluid would be thicker, and there would be shreds of lymph. It might be the same color, but it would contain more leucocytes. So that from all points —the pulse was never over 100—we conclude that there was not general peritonitis.

Again, if there were, there would be some adhesions which would interfere with the complete change of the level of dullness on movement, which was complete in this case. I have seen cases where an injury to the abdomen has been soon followed by enlargement, with a firm and unilateral swelling and subsequent ascites, which has recurred and resulted in a general thickened condition over one side. Here there has been an effusion of blood, exudation of serum from it, absorption, with the permanent deposition of layers of thickened fibrin. In this case I think there has been some change in the liver from his habits of excess, some cirrho-

sis, but not enough to cause the ascites which was superinduced by the fall, which caused a local peritonitis near the portal vein, with inflammation of its coats and obstruction. The test for indican is to mix the liquid with an equal amount of hydrochloric acid, and add a little chloroform, when we get a bluish-purple color. On December 15 he was given sulphate of soda, which moved the bowels, but the ascites increased. He was then given $\frac{1}{12}$ gr. elaterium, and $\frac{1}{3}$ gr. extract belladonna, with some oil of cajuput to prevent griping. The elaterium was repeated, and he had copious watery stools, but the oppression so increased that he was tapped, as stated. Now, thirty-six hours after the operation, the belly is apparently filling again. The prognosis is a doubtful one. If he was perfectly healthy I would have great hopes; but I am satisfied from his history, and from the condition of the capillaries, that the liver is at least engorged, and very likely in the stage of incipient cirrhosis. But if the channel of the portal vein is not entirely occluded, he will make a slow recovery. The treatment must consist in long-continued counter-irritation, a blister three inches square over the fissure of the liver, opium for pain, and the mild chloride of mercury. Cinchona sulph., by enema, eight grains twice daily, and $\frac{1}{2}$ grain powdered opium, and $\frac{1}{4}$ grain of the mild chloride thrice daily, to be continued for some time. I am an earnest advocate of early paracentesis. I very much prefer small and frequent tappings, to waiting until life has been rendered miserable by enormous distension. This man's diet will be skimmed milk and broths. I will not rely on purgatives to get rid of the fluid, but I will not hesitate to tap as often as may be necessary. Dr. Packard has recently invented a most convenient glass tube, which can be left in, with a fine tube attached; it will not rust; it is pure and antiseptic.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. Parvin.

Lacerated Perineum and Hypertrophy of the Neck of the Uterus.

I show you a case upon which I operated four or five weeks ago. I amputated the hypertrophied neck of the uterus and sewed up the perineum. The perineum healed up all but a small space, which I foolishly tried to pare from the inside and stitch together; that procedure, I am glad to say, was a failure, for I never should have tried it. I now cut out a small ring of tissue surrounding this orifice, and bring the edges together. For half an hour before this woman was brought into the room, I applied a five per cent. solution of cocaine. Either it has had a marked anæsthetic effect, or the woman is very heroic, for you observe that she does not flinch. We will order hot water injections, and give ergot with nux vomica to procure contraction of this womb, which is still quite large, though the amputation has reduced it from five to three inches.

Epithelioma of the Uterus.

This woman has had several lacerations, but the case illustrates the fact that lacerations are not the cause of epithelioma, as some contend; the disease has occurred independently of them. As a guide to prognosis in these operations, I would state that in twenty-four out of every one hundred operations there is no return up to within one year after the operation. I will here use the galvano-cautery knife in preference to the wire, because with the latter I could only make a transverse incision, while here the disease extends well up on the anterior lip, and a transverse incision would not remove it. If you hurry with the galvano-cautery, you are sure to have hemorrhage. The stream of electricity must be intermitted every couple of minutes, when you will syringe out the vagina with cold water, as a protection.

Medical Societies.

BALTIMORE ACADEMY OF MEDICINE.

Stated meeting held December 1, 1885.

The president, Dr. J. J. Chisolm, in the chair.

After the regular order of business, the following cases were related:

Evisceration of Eye-ball by the New Method.

Dr. J. J. Chisolm related a case of evisceration of the eye-ball after the plan recently recommended. The operation consists in completely excising the cornea by means of a circular incision around its margin. The contents of the ball are then to be entirely removed, leaving the sclerotic intact. The advantage claimed for the operation is that the socket tissues are not disturbed, neither is the muscular apparatus of the eye interfered with; besides, the stump

left after cicatrization leaves an admirable seat upon which to locate the artificial eye. The operation itself is a very simple one, and can be performed much more expeditiously than can complete enucleation, but convalescence is so very tedious, and at times gives rise to such painful and alarming symptoms, as occurred in his case, that in future he will confine himself to the old plan of complete enucleation.

Dr. Chisolm said that it was his usual custom to allow a patient to go about his affairs very soon after the operation, at the outside, twenty-four hours; but in the evisceration operation, even up to the fourth day and later, there was such œdema and pain that he could not think of allowing the patient to be from under his observation. He had never had such an experience with the old method.

Dr. S. C. Chew wished to know if sufficient anæsthesia could be produced by the use of cocaine to enable one to perform this operation without painful sensations on the part of the patient.

Dr. Chisolm thought not.

Paralysis the Result of a Fall.

Dr. A. B. Arnold related a case which occurred at Bay View Asylum a year ago. It occurred in a woman five months pregnant. She fell from the second-story window, striking upon the head; when picked up she was senseless, and remained so for three days. Among the consequences of the fall abortion was brought on. At present she has paralysis of both lower extremities, complete anæsthesia on right side, is deaf and also blind on this side.

She evidently had some spinal trouble, as she complains of that sensation so common to these troubles, "as if a belt were being drawn about the waist;" also has some enfeeblement of the sphincters of bladder and rectum. In addition, there is a peculiar nervous jerking about the head, which has continued for one year.

Dr. Arnold thinks the lesion is located about the inferior third of the internal capsule, extending up and involving the optic and anditory nerves at the point of crossing, and also does he take the nerves of sensation which come off at this point to be affected. He thinks the symptoms justify this conclusion. The pupils responded normally to light. She had never had any trouble previous to the fall.

Dr. Chisolm asked if any ophthalmoscopic examination had been made. He said he was prompted to ask this question by a case which recently came under his observation. It occurred in a man who had received a severe beating, and among the results loss of vision began after about six weeks.

He examined him, and found anæsthesia of the fifth nerve, the hearing involved, and several small retinal hemorrhages around the point of entrance of optic nerve.

Dr. S. C. Chew related an interesting

Case of Empyema.

He had been called in consultation to see a case which occurred in a patient who for several days past had suffered from severe dyspnœa The night before he saw the patient he had had copious expectoration of matter, the nature of whieh he could not describe as it was not saved. This was followed by immediate relief from the difficulty of respiration.

Upon physical examination of the chest, the left pleura was found to be about two-thirds filled with fluid. Shortly after his visit the patient suddenly died, with profuse vomiting of purulent matter, as well as the passage of quantities of it from the bowels. From such symptoms, he thinks it highly probable that perforation took place through the diaphragm into the stomach, and that the fluid was discharged in both directions, through the œsophagus and through the intestines. He had searched the literature on the subject, and had found no case terminating in this manner recorded. Physical examination of chest made before the first expectoration of matter showed the pleural cavity to be entirely filled with fluid. More recently he had seen a patient at the Baltimore Infirmary, whose physiognomy was indicative of pulmonary trouble. Percussion over right side of chest gave decided resonance both anteriorly and posteriorly. On auscultation on same side there was pronounced *Hippocratic Succussion.* Shaking the patient while the ear was still on the chest gave a sound very similar to that heard when one shakes a jug partly filled with water. No discomfort at all was noticed, neither pain nor dyspnœa. He thought the absence of dyspnœa could be explained on the ground that the air probably distended the pleura (and this compressed the lung) so gradually that this lung as well as the healthy one had sufficient time to accustom themselves to their abnormal relations. Whether perforation was due to ulceration outward through the pleura, from the wall of the cavity in the lung, or whether it was due to a loss of substance occasioned by a point of inflammation upon the visceral

pleura, and thus perforation taking place in the reverse direction, he could not say, although symptoms sufficiently marked were present to point to either mode.

In his opinion, surgical interference should be resorted to as soon as the condition of empyema is made out.

Dr. Arnold has seen a case of empyema in a child. It occurred on the right side, ulcerated through the diaphragm, and discharged its contents into the abdominal cavity. The child died from shock. He considered it somewhat remarkable how rarely phthisical patients showed any signs of discomfort from interference with respiration, even though their lungs might be riddled with cavities.

Dr. Chew looked upon this as due to the slowness of the pathological process, this enabling that portion of the lung which is healthy to increase its physiological activity. He also thought, in view of the fact that cavities so frequently form near the pleura, that it was singular that we so rarely found perforations from them.

Dr. Chisolm said serous sacs resisted perforation.

The Cocaine Habit.

Dr. J. C. Thomas said since he had been told that in some of our principal cities the cocaine habit was largely being acquired, he would like to ask if any member had ever seen a case of it?—and if the report is true, did not the gentlemen think that the medical profession should take some steps to prevent the reckless prescription of this seductive drug?

Dr. Chisolm related two cases in which decided loquacity was produced by the introduction of cocaine into a cavity in a decayed tooth. In speaking of *cocaine tablets*, he referred to a condition amounting almost to a slough, that was produced on the buccal surface of his own cheek from the application of one of these tablets to the gum and allowing it to remain until dissolved. From this, he hardly considered them the thing to use in nasal catarrh.

NEW YORK NEUROLOGICAL SOCIETY.

Discussion on Dr. Hammond's Paper. (*See page* 6.)

Dr. Leonard Weber related a case which he thought would interest Dr. Hammond, as going to support the view which he seemed to entertain, that unilateral hallucinations were not associated with disease of the special sense concerned, but with an affection of central origin. The man came under his observation in 1879, at which time he was 37 years of age, strong, healthy, very active in business, but in consequence of domestic trouble and mental strain, he began to lose sleep, was sensitive to strong light, loud noises, etc., and from 1879 to 1881 was subject to hallucinations connected with the left ear. On going to bed he would be unable to sleep for two or three hours, because of whispering noises, growing louder and louder, heard in the left ear, and of two kinds, one soothing and another demandatory. A careful examination by himself and by a specialist in diseases of the ear, failed to reveal anything wrong connected with the auditory apparatus. When the patient's circumstances changed, and he was enabled to lead a peaceful life, the hallucinations disappeared, and had not returned.

Dr. E. C. Spitzka had not heard the entire paper, but being familiar with the author's views regarding the function of the optic thalamus, he was somewhat surprised that he had not tried to harmonize his observed facts with the anatomical and physiological facts which had been incontestably established during the past decade. Lewes, upon whom Dr. Hammond probably rested chiefly for support of his views, expressed his ideas regarding the functions of the optic thalamus as many as twenty-five years ago, and what he wrote was mere guesswork. If he had been supported in part by recent accurate methods of research, such as the atrophy and other methods, it was a mere coincidence. Dr. Spitzka said his own views regarding hallucinations were directly opposed to those of Dr. Hammond. He believed that hallucinations had their seat in the cortex, and not in the optic thalamus or any of the lower ganglia. The optic tract and thalamus might have undergone secondary atrophy, following enucleation of both eye-balls, yet the person would be capable of having hallucinations, showing that hallucinations had not their seat in the optic thalamus. The case cited by Dr. Hammond in which, during her hallucinations, the patient saw the figure of a man and woman, showed the exercise of mental qualities which could have their seat nowhere else than in the cerebral cortex. Dr. Hammond had asked whether he did not believe a hallucination to be something which had been previously registered in the memory, and which was projected outward. He would reply that, without quibbling with terms, that was precisely what he meant by a hallucination.

Dr. M. A. Starr related the facts in a case reported by Vetter, in which a patient having a right hemianopsia imagined that she saw people sitting at her right side, which was the blind field of vision. By a process of exclusion it was shown that the lesion could not have existed in the optic thalamus, but must have existed in the occipital lobe. Dr. Starr thought that in all probability the source of the hallucination in this case was cortical irritation. Certainly in a great many cases cortical irritation would produce hallucinations. This was observable in meningitis in which the optic thalamus was not implicated.

Dr. W. M. Leszynsky recalled the case of a woman in an insane asylum, fifty years of age, suffering from mania, who was in the habit of sitting hours at a time with the left ear inclined toward a table, sending, she said, and receiving telegraphic communications. She did not receive the telegraphic communications with the right ear, which she said was only for general use. Hearing seemed to be normal; perhaps that in the left ear was a little more acute than that in the right ear.

Dr. Sachs referred to a case of hemiplegia with tumors in the optic thalamus, reported by Minot, and asked Dr. Spitzka whether he could imagine an excitation of the cerebral cortex, giving rise to an image of hallucination, the revival of such image not being due to an antecedent peripheral irritation.

Dr. L. J. Corning asked why hallucinations which might be produced by impressions coming from the peripheral nerves might not also be produced by an irritation at any point in that peripheral tract, as in the thalamus. We would all admit that the higher forms of conception took place in the cerebral cortex.

Dr. C. L. Dana would like to hear the subject discussed which Dr. Hammond probably wished to bring before the Society, namely, the duality of the brain. So far as the mechanism of hallucinations was concerned, he thought all would agree with Dr. Spitzka, that it was essentially in the cerebral cortex, but the exciting cause might be a peripheral irritation acting upon the psychopathic centres.

As to the duality of the brain, he thought there were many more arguments against the proposition than for it; but the subject was one of great reach, and could hardly be discussed at this hour. The cases of hallucination cited did not, it seemed to him, prove much, because only a small part of the psychical mechanism was involved. On the other hand, the experiments of Dumont Pare proved little, because hypnotized subjects could be led to do almost anything by slight suggestion. But pathological observations, the results of hemi-atrophies, of tumors on one side of the brain, studies regarding language, etc., all went to show that the two cerebral hemispheres had certain distinct functions, and that there were not two halves of the brain each having about the same function.

Dr. Charles Heitzman said that although he was not a specialist in this department, he had given considerably study to it; and he had received the impression that neurologists were not entirely clear in their ideas concerning the seat of irritation which caused hallucinations. Let the physiological fact be remembered that an impression upon our senses can be brought forward at any time in the shape of a protracted sensation or hallucination. Thus a peculiar sound might be heard which was merely the image of a real sound, and constituted a hallucination. Everything which we have learned is deposited in the brain, especially in the gray substance. In the case of the black cat, could the man have had a hallucination of a black cat if he had never seen a black cat? I doubt it. Wherever the centre for the image of the black cat may be, if any portion of the nerve tract leading from the retina to that centre be disturbed, it will be likely to excite that centre, and the image of the black cat will be revived. The special point of interest connected with the cases related was that they were unilateral. He asked if that might not be explained on the supposition that the irritation being upon one side led to the centre for the given image upon that side only.

Dr. Spitzka said, with regard to the quality of mind, that there could be little difference of opinion regarding the following facts: First, that the two cerebral hemispheres were alike in structure, the variations being no greater than in other symmetrical organs, if allowance be made for a higher type of development; the hemispheres were united by a symmetrical commissure; they had corresponding peripheral tracts; they had about the same distribution of retinal fields. Post-mortem examinations on the insane went to prove that the hemispheres were symmetrical. One hemisphere might be practically destroyed, and yet the individual retain power to exercise the several faculties of the mind, as reasoning, memory, judgment, etc., not, however, that

there would be no paralyses or other symptoms. But it was a different matter entirely when it was suggested that unilateral hallucinations could exist when the corresponding hemisphere was perfectly healthy.

Dr. Hammond, in closing the discussion, said it was not his object in reading the paper to discuss specially the function of the optic thalamus. He might say, however, that he believed a person could have hallucinations without an optic thalamus at all, provided he had a cortex; but he believed, also, that he could have hallucinations without any cortex, provided he had an optic thalamus. In the former case, the hallucinations would be due to revival of past impressions; in the latter case, they would be original, having nothing to do with former associations. A man without an optic thalamus could have an idea of a cat in the abstract, but he could not have a hallucination of a particular cat unless he had an optic thalamus. He believed that ideation resided in the cortex. With regard to the duality of the mind, many arguments might be brought forward, but time would not permit.

Periscope.

Sarcoma after Injury.

In connection with the case of sarcoma which we recently reported from the clinic of Dr. Agnew, the following, which we take from the *Brit. Med. Jour.*, November 28, will be read with interest:

Before the Medical Society of London, a paper on the developmont of sarcoma shortly after injury, founded on three cases recently observed, was read by Mr. A. Pearce Gould. The first was that of a girl aged 16, who, three months after she had struck her forearm, noticed a swelling of the upper end of the radius, which enlarged rapidly under observation till it involved the upper third of the bone. Puncture of a fluctuating area with an aspirating needle resulted in the withdrawal of some bloody fluid. The patient made a good recovery. The tumor was found to consist in great part of a large blood-cyst. On microscopic examination, its structure was seen to be that of a myeloid sarcoma. The second case occurred in a woman aged 26, who, three months previously, had struck her thigh. Two months later, a swelling was apparent, and steadily increased, so that, when first seen, the whole bone was involved, and the tumor had attained a large size. The tumor was situated on the outer side of the bone, but, on section, was seen to extend into the medullary canal. It contained several blood-cysts, and was in part ossified. The limb was amputated by a modification of Mr. Furneaux Jordan's method. Soon after amputation of the thigh, recurrence of the growth occurred in the groin. The secondary tumor was excised, but the disease had recurred in the stump. The third patient was a man aged 70, who, on October 29, 1884, struck his arm and elbow. He was admitted into Hackney Infirmary, and treated for contusion. On November 18 he was discharged, but was readmitted in February on account of pain and swelling of the arm. The humerus was greatly enlarged and broken. It was put up in splints; but the swelling rapidly increased, and the limb was amputated. Mr. Gould quoted a considerable number of cases where sarcoma appeared soon after injury, recorded by various writers. It was important, he said, to class separately those cases in which growths followed, not after repeated slight injuries (irritation), but a single injury. He confined his remarks to the first class of cases, and observed, in the first place, that the relation between the injury and the growth was not accidental, though the injury itself was not the all-sufficing cause. To state that the patients were predisposed to the growth of such tumor, did not account for the fact that such patients had previously received many injuries—perhaps in the very same part—without the development of a tumor. The cases occurred most frequently between twenty and forty years of age, an age when injury was most frequent, and in those bones which were most exposed to injury.

Mr. Harrison Cripps referred to three cases already recorded, where sarcomatous growth followed directly on injury; in all the cases there was bruising, and he thought that bruising of the tissues was an invariable antecedent of the development of tumor in

these cases. He thought that pyæmia afforded an analogy to these circumstances; the most striking clinical difference was the greater length of these cases of so-called traumatic malignancy; the most striking pathological difference was that, in pyæmia, the new cells being rapidly formed broke down, whereas, in sarcoma, the newly-formed material did not break down, but was more or less organized. He suggested that in these cases of malignant traumatic sarcoma, an infective organism might play some part in the origin and dissemination of the disease.

Mr. Davies-Colley related the case of a boy, aged 15, who sustained a fracture of the thigh; two months later, a swelling appeared and the union of the bone was found to be imperfect. As the swelling was fluctuating, it was incised; bleeding continued for some time; the limb was amputated, but the patient succumbed. The amount of new growth was very small in the bone and the muscles around, but there were secondary growths in the lungs and kidneys. He praised Mr. Furneaux Jordan's method of amputation.

Mr. Geo. Lawson said that injury was a frequent antecedent of new growths, and he made no doubt that sarcoma, scirrhus, and epithelioma might follow directly on injury.

Mr. Barwell said he believed he was the first to apply the term traumatic malignancy to this class of cases. He had seen six cases in which there was an extreme tendency to keloid growth, in connection with acne punctata, and quoted one in which one of these small keloid tumors enlarged rapidly, and was found on removal to be sarcoma. He adopted the theory of the existence of tumor diathesis, or predisposition to the formation of new growths. He thought Mr. Furneaux Jordan's method of amputation gave good results.

Mr. R. W. Parker considered that Mr. Furneaux Jordan's method of amputation was very advantageous in children. He thought that in the causation of these cases of sarcoma after injury, the existence of a predisposition must be admitted. He had frequently observed the development of sarcoma in connection with blood-clot, and suggested that the growth might have its origin in the leucocytes of the blood-clot.

Mr. Royes Bell dwelt on the difficulty of diagnosis. He quoted several cases where mistakes had been made. Sir Joseph Lister's method of amputating by a long oval incision was a very satisfactory operation, though rather tedious.

Mr. J. Bland Sutton related a case where sarcoma of the tibia occurred ten years after an injury inflicted by a spent cannon-ball, and observed that it was only in cases where there was some special circumstance serving to fix the injury in mind, that the connection could be ascertained. Sarcoma was very frequent in animals, from fish to men; the situation in which the growth occurred in various species varied with the species, but always occupied a position which, in that species, was peculiarly liable to injury. The clot formed after contusion might organize perfectly or imperfectly, or remain ill-formed tissue to the end, or it might act as what Cohnheim called a tumor-germ, and might be the starting-point of a generalization.

Mr. Gould, in reply, said that his method of amputation differed from Mr. Furneaux Jordan's, in that he made a circular incision as for amputation through the upper third of the thigh, and tied the vessels; then he made an incision upwards to the trochanter, and enucleated the head of the bone.

Malignant Nasal Polypus Treated by Furneaux Jordan's Operation; Remarks.

This case is reported in the *Lancet*, November 28, 1885:

D. B——, aged sixteen, came to the outpatient room on August 11, 1885, with a fleshy, highly-vascular growth protruding from the anterior nares, and bulging outwardly the right nostril. He had only noticed it for a fortnight. Mr. Fowler removed what he could with a snare, and controlled the copious hemorrhage that followed by plugging the anterior nares with cotton-wool.

On September 18, Mr. Fowler saw him again. The growth had recurred, and was larger than before. It could not be felt in the pharynx. It had begun to grow a fortnight after removal, and the boy had suffered from repeated attacks of epistaxis. The first growth, examined microscopically, showed the structure of an alveolar sarcoma. The tumor being thus both clinically and structurally of a sarcomatous nature, and probably growing from the roof of the nasal cavity, Mr. Fowler decided to perform the operation recently described by Mr. Furneaux Jordan. His colleague, Mr. Wilders, put one of his beds at his disposal.

On September 24, the patient being under chloroform, a sharp-pointed curved bistoury was carried under the upper lip into the affected nostril, and made to cut its way out. The soft part of the nose was similarly

transfixed, and divided just externally to the median line in a line with the cut in the lip. A few touches with a scalpel allowed the triangular flap thus formed to be turned well outwards, so as to completely expose the bony orifice of the nasal cavity. The hemorrhage being controlled, the projecting portions of the growth were torn away. With the index finger it was then possible to explore the whole of the roof of the naso-pharynx, and scrape away with the nail the attachments of the growth from the roof of the nasal fossa, leaving it perfectly clear. The nose and lip were then carefully and accurately readjusted with fourteen fine silver wire sutures.

The patient was discharged from the hospital six days after the operation. He was seen on October 7. There had been no recurrence of the growth, and the site of the incision was denoted by a very narrow linear scar of a delicate pink color.

Remarks by Mr. Fowler.—Of course, it is yet too soon to speak of a permanent cure. I have brought forward this case, not so much for its clinical aspects as for a testimony to the usefulness of the operation. I decided on this method from faith in the advice of my friend and colleague, Mr. Furneaux Jordan; and I must confess that from the memories of my anatomical skull, I fully expected to have to enlarge my opening by snipping away the nasal bone. I was surprised and gratified, however, to find that I had plenty of room. Being able to thoroughly explore the roof of the naso-pharynx with one's forefinger is no doubt due to the bulging of the cavity that occurs in these growths; and also in this individual case to a deep erosion of the middle turbinated bone. I can thoroughly recommend this operation to my brother surgeons, as being, in Mr. Furneaux Jordan's own words, "efficient, simple, and followed by but little scarring."

Hemorrhagic Amblyopia Cured by Dilatation of the Sphincter Ani.

Dr. Robert N. Hartley thus writes in the *London Med. Times*, November 28:

The following case seems to me to well illustrate two points, first, the serious amount of amblyopia liable to be produced by frequently recurring hemorrhages, extending over a long period of time; and second, the value of the surgical procedure of free dilatation of the sphincter ani under ether. A man holding a responsible position in one of the large leather factories of this town consulted me in June last on account of a gradual loss of sight. He thought he was "going blind," and that he should be obliged to resign his situation. As a matter of fact, there was very serious visual defect, the distant vision of each eye being only equal to $\frac{20}{70}$, while no type smaller than No. 14 Jæger could be read. There was nothing in the appearances of the eyes (ophthalmoscopic or other) to account for so much defect, except a slight pallor of the discs. From his appearance, I suspected that he might be suffering from loss of blood in some way, and a little close questioning elicited the following facts:

For *ten years* he had suffered from repeated bleeding of the anus. The bowels were *never* moved without great pain, and seldom without bleeding, sometimes slight, but often profuse, and the last three months he had frequently to leave his work and go home on account of severe bleeding, which saturated his clothes, etc. He was constantly taking either purgatives or astringents. Introduction of the finger into the bowel caused such intense pain that a thorough examination was impossible without an anæsthetic. I told him that I thought the failure of sight was due to the bleeding, and advised that this should be treated. Accordingly, in a few days, he was put under ether, and I found an enormously powerful sphincter ani, the internal fibres being especially marked as rigid rings extending for some distance up the bowel. I freely and thoroughly stretched with the fore and middle fingers of each hand the rigid sphincter until all sense of resistance had ceased, and all the fingers of one hand, in the form of a cone, could be easily pushed into the rectum. The congested and swollen mucous membrane now protruded, and the surface of it was seen to be here and there marked by irregular ulcerated patches, which had no doubt been a chief source of the hemorrhages. Nothing more was done except the swabbing of the parts with carbolized glycerine. After three days' rest in bed, the bowels moved spontaneously for the first time since the operation, with little or no pain, and with no bleeding.

Six weeks afterwards he came into my consulting-room, and said: "I feel a new man; I have never bled *once* since I had the ether; I have never had a dose of medicine, and my bowels act every morning without pain or difficulty."

He still remains (October, 1885,) in the same happy condition, and his acuity of vision is now perfectly normal—$\frac{20}{20}$ and J. 1.

The Effects of Cold Saline and Fresh Water Baths on Fever.

The *Lancet* (Dec. 5th) says that the treatment of fevers by baths, of which a good deal has been heard during the last few years, is of course by no means novel, being mentioned by Hippocrates, Galen, Celsus, and other classical writers. Currie, in 1787, obtained excellent results by treating "typhus" in this way, and several continental physicians shortly afterwards followed Currie's example. Within the last five-and-twenty years, many careful observations have been made with the assistance of modern instruments of precision, as the clinical thermometer and the sphygmograph, on the effect of cold baths—that is to say, baths considerably below the temperature of the body—in cases of fever, and especially of typhoid, both of an ordinary kind and where the temperature was abnormally high; and papers on the subject have been published by Brand, Ziemssen, Wilson Fox, Bartels, Jurgensen, Hagenbach, Liebermeister, Mosler, Treskoff, Chesnokoff, Nikolski, Krukenberg, Stöhr, Ringer, Bradbury, and others. Senator added to the water of the bath, two pounds of potash and half a pound of soda, but did not, however, find that these materially improved the results. He then applied a sinapism before putting patients in the bath, and obtained better results. Winternitz then tried the effect of rubbing the surface pretty energetically just before the bath, and showed, by means of comparative experiments, that while after a simple bath the temperature of a patient was lowered to 0.2° C., after a bath of similar temperature and duration preceded by friction it was lowered 0.8° C. Last year Dr. Liskus, of St. Petersburg, published the results of observations on thirty "parallel baths at 20° R. (87° F.)" with and without friction, showing that the temperature, both in the rectum and axilla, was more distinctly lowered and for a longer time where friction preceded the bath than where it was not employed. Quite recently Dr. Rabinovich has published the results of some very extensive investigations made in the Nicholaevesky Military Hospital on the comparative effects of salt and fresh water baths on the temperature, pulse, respiration, and muscular power of twenty-six typhoid fever patients to whom he gave 141 baths. He finds that saline baths have more effect in lowering the temperature than fresh water ones, the average difference being rather more than a tenth. It is especially great during the first half-hour after the bath, but is perceptible for fully three hours. Evening baths, both saline and fresh, produced a greater reduction than those given in the morning. Saline baths produced a more marked effect on both pulse and temperature than fresh water ones. The augmentation of the muscular force as tested by the dynamometer was also greater with the former class of baths.

Theory of Cancerous Inheritance.

In a paper before the West London Medico-Chirurgical Society, Mr. Dunn combated the alleged heredity of cancer. Beyond the consecutive appearance of the disease in certain families, cancer fulfilled, in no sense, the characters of an hereditary malady. It included no physiognomic aspect, diathesis, or general condition, seen in true hereditary diseases, as gout, syphilis, and tubercle. There was no such thing as a cancerous stomach, a cancerous neuralgia, a cancerous ache or pain, without local objective cancer, and no patient was cancerous till he had the local and tangible symptoms of primary cancer. In these points, cancer entirely differs from hereditary diseases.

Mr. Butlin, after expressing the interest with which he had listened to the papers of Dr. Alderson and Mr. Dunn, stated that the memorandum which he (Mr. Butlin) had drawn out for the Collective Investigation Committee, in which, among other things, certain questions were asked in regard to the inheritance of cancer, was not intended to convey the expression of any decided opinion upon the matter. It was merely for the purpose of eliciting facts. Of course, he had his own views upon the subject. Speaking personally, he did not agree with the adoption of the hereditary theory of cancer. Amongst the upper classes, it was looked upon as a great calamity if a case of cancer occurred in the family. He was of opinion that the locality in which the person resided was most important, and that residence had a most powerful influence over the disease; but he also considered that there were other factors of great moment which predisposed to cancer, such as, amongst others, smoking, diet (good or bad), anxiety or worry, that it was from a combination of these rather than from any single cause that predisposition arose. In addition to the above influences, he would also mention that important factor in health, namely, the soil of the locality, and the way in which it was drained and manured.

Mr. Keetley said that, in the investigation

of cancer as to its causation, hereditary or otherwise, great care was required, as it was an exceedingly complex question. In a collective investigation of the predisposing causes of cancer, he considered that an inquiry in each district and in each neighborhood should be considered separately.

Mr. Lloyd was of opinion that locality was an important factor in the causation of the affection under discussion.

Dr. Alderson, in reply, said that he thought that the importance of the heredity of cancer was considerably overrated, inasmuch as, whilst many families were undoubtedly tainted with the disease, it nevertheless occasionally never manifested itself in any way. It was of the utmost importance that the predisposing causes should be fully investigated.

Fatal Case of Pemphigus.

Dr. T. G. Parrott thus writes in the *Brit. Med. Jour.*, November 28, 1885:

Ambrose B., aged thirty-three, a Spanish-American and man of color, was seen at his home on August 15th. He had been under the care of a homœopathic practitioner for three weeks. His condition was as follows: There were numerous sores, covered with scabs, on his face and scalp; each eyelid was occupied by a sore with free discharge; his neck, chest, thighs, legs, and arms were covered with bullæ in various stages; one long narrow bulla on the left forearm looked as if caused by the application of a hot bar to the skin. The majority of the bullæ were rather smaller than a threepenny piece, of dark red color, and contained some discolored serum; they were situated on very slighty inflamed bases; others had burst and formed scabs. The friends said that the bullæ had appeared in successive crops. The eruption began first on the inner and upper part of the thighs. The whole of the back was raw, large bullæ having been formed and burst. The attack was preceded by rigors and vomiting. The pulse was 124, and temperature 99.4° Fahr., and the patient was in a very weak state. The following day he was removed to the hospital, and placed on a warm bed, the sores being dressed with boracic ointment, and a mixture was given containing iodide of potassium, liquor arsenicalis, and bark. On the 17th he said he felt better, though much troubled with flatulence. Temperature, morning, 101.6° Fahr.; evening, 102.4° Fahr. On the 18th he had rather severe diarrhœa, the stools being copious, pultaceous, and light colored, resembling those of typhoid fever. Temperature, morning, 102° Fahr.; evening, 101.6° Fahr. At midnight, a change for the worse took place; his pulse became irregular, fluttering, and too quick for counting, but after a dose of brandy it was 136. The bowels continued freely open; he gradually sank, and died at 5 a. m. on August 19. No post-mortem examination was allowed. He was said to have suffered from disease of the lungs, but no examination of them could be made in the state in which he was. There was some cough.

Remarks.—This case seemed to be one of acute pemphigus of very severe character, with typhoid symptoms at the last. There had been a case of typhoid fever in the same house at the time he was taken ill, and therefore the blood-poisoning was probably of a typhoid nature. There was no history of syphilis.

Lagophthalmus Due to Dental Irritation.

At the November meeting of the Odontological Society of Great Britain, Mr. S. J. Hutchinson related the following interesting case of reflex nervous disturbance caused by dental irritation. The patient, a lady, was sent to him by Dr. Gowers, in October, 1883, with a request that he would examine her teeth, and see if he could discover any probable cause for a spasm of the left eyelid, from which she had suffered for several months. The eyelid was drawn up by a constant spasmodic contraction of the levator palpebræ in such a manner that not only the whole of the iris, but also a considerable amount of the white round it, was always visible. Mr. Hutchinson found the patient's teeth in a bad state. The left second and third molars, both upper and lower, were much decayed, and Mr. Hutchinson extracted all four; but, though the patient no longer suffered from neuralgia, as she had before, the spasm of the eyelid was not in the least diminished. There did not appear to be anything amiss with the other teeth on that side, except that the upper first molar contained a large amalgam stopping; but, as the tooth had never given her any pain, the patient would not consent to its being interfered with. She then returned to her home in the country, and Mr. Hutchinson saw nothing of her for more than a year. When she again presented herself, the eye was in the same condition, and Mr. Hutchinson again failed to find anything in the mouth likely to be a source of irritation except the amalgam stopping in the left up-

per first molar. After some persuasion, the patient allowed Mr. Hutchinson to remove this, and he then found a minute exposure of the pulp on which the filling had evidently pressed. Mr. Hutchinson advised the removal of the tooth, and the result was most satisfactory. The patient's appearance at once began to improve, and, at the end of six months, the difference between the two eyes was so slight that it would not be noticed by a casual observer. It was evident, therefore, that in this case reflex irritation of the third nerve had been caused by irritation of a branch of the fifth, and this in the absence of any symptoms referable to the tooth.

Rupture of the Vagina.

Dr. George E. Thompson thus writes in the *Med. News*, Dec. 19:

I wish to report, in addition to those mentioned recently in the *Medical News*, another case of vaginal rupture which occurred in a girl nineteen years of age, as the result of coitus. The same man had had intercourse with her once before and, with the exception of considerable pain, without any bad result. This time, however, the pain was very severe, and the act was followed by a profuse hemorrhage, which still continued when I saw her eighteen hours after. I found her in a bed which was soaked in blood. She was very anæmic, much exhausted, and had a weak, rapid pulse. On examination, I found no bleeding at the hymen, but about an inch beyond, on either side, were several longitudinal fissures, from half an inch to an inch in length, from which the blood was oozing at the rate of a teaspoonful in two minutes (vaginal distention by the speculum probably increased the flow to some extent). The bleeding was stopped by packing the vagina with tampons saturated with liq. ferri subsulphatis.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The employment of bromide of ethyl or hydrobromic ether as an anæsthetic is discussed by Dr. Lawrence Turnbull in a reprint before us. It is probable that there is no person in our country who can speak on this subject from a wider and more intelligent observation. The conclusions at which he arrives are not unlike those which he announced as far back as 1870, and may be briefly summed up in his own words as follows:

"Bromide of ethyl should never have taken the place of chloroform or sulphuric ether where any tedious operations are to be performed; but there is no reason why this useful anæsthetic should not be employed in all operations in minor surgery and in those on the eye, ear, throat and nose, having everything ready in advance so that the patient shall be as short a time as possible exposed to the evil effect of an anæsthetic."

——Mr. Reginald Harrison, F. R. C. S., of Liverpool, has reprinted from the *British Medical Journal* the description of a method of treating urethral stricture by combining internal and external urethrotomy. The plan is ingenious, and appears to have met with success.

——Dr. D. W. Cathell, of Baltimore, sends us a reprint setting forth in warm terms the advantages of medication by the rectum over that by the mouth in many cases. He is certainly quite right in his position that this convenient and efficient method is too much neglected, and we hope this article will call more attention to it.

——Dr. Donald MacLean, President of the State Medical Society of Michigan, at the last meeting of that society delivered an address on the mutual relations of the medical profession and the state, which has been printed by the society. It is a thoughtful production, and merits careful reading by all interested in the important questions it broaches.

BOOK NOTICES.

Clinical Notes on Uterine Surgery, with Special Reference to the Management of the Sterile Condition. By J. Marion Sims, M. D., etc. 8vo., pp. 401. Price, $1.00. Wm. Wood & Co., New York, 1886.

This is the same work which was published in 1873, and is apparently printed from the same plates, the title-page bearing the date just named. It is, however, issued in paper at a reduced price as a "memorial edition." Undoubtedly it is one of the most characteristic and original of Sims' productions, his management of sterility being much more his own than his operation for vesico-vaginal fistula. Many physicians will be glad of adding this treatise to their library at the moderate sum asked for it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street, Philadelphia.

THE NEW YEAR.

It is occasionally a pleasant pastime to forecast the future, to wit., when there are good grounds for taking a cheerful view of it. Certainly that is now the case for the general business interests of the United States. Merchants in this city who have the best means to acquaint themselves with the movement of values, tell us that the volume of business, taking the whole country over, is greater now than at any previous period in its history. True, they add, the percentage of profit is less than in years gone by, but to the cautious citizen this is rather matter of congratulation than otherwise, as the facility of getting rich quickly is, in the long run, an injury to society.

This general condition is reflected in the status of the medical profession. Never before were there so many thoroughly educated physicians among us; never was the standard of our medical schools so high; never were our hospitals, sanitary institutions, and boards of health, so numerous, so well supported, and so efficient.

Perhaps we are too much given to underrate our progress in these directions. Comparing ourselves with some of the much smaller and much older countries of Europe, still more, comparing ourselves with our own ideals of perfection in these respects, we may be tempted frequently to speak with something like contempt or despair of our advancement. It is a decided error of fact so to do. Any intelligent physician who has had the advantage of some public position bringing him largely into contact with his professional brethren for the last quarter of a century, cannot fail to acknowledge the enormous, the surprising advance that has been recorded.

This growth will not cease nor diminish. On the contrary, it will become more marked year by year, and the year on which we are now entering bears every promise of adding not a little to the general sum of professional improvement. We trust that all the profession, and especially all our readers, will have cause to acknowledge the truth of our forecast, when the year 1886 draws to a close.

THE PRACTICAL VALUE OF ESTIMATING THE AMOUNT OF UREA PASSED DAILY.

We have often wondered when we read clinical reports and witnessed eminent clinicians make examinations, why more note was not made of the amount of urea passed by the patient. It is the retention of this product of retrograde metamorphosis that works the mischief in Bright's disease, and the detection of casts and the presence of albumen do not indicate to us how well or how poorly the kidneys may be doing their work.

By their presence we simply know that there is a congestion and a degeneration of the kidney, which we assume hampers its function, but we do not thus learn how serious or how slight may be this hindrance. Therefore do we note with pleasure the article in the *Brit. Med. Jour.*, Dec. 5th, by Dr. W. E. Green, wherein he insists upon the importance of estimating the amount of urea passed daily. Dr. G. says:

"Having made these preliminary remarks, I will now show you Dr. Squibb's apparatus for the approximate estimation of urea in urine, and describe the method of using it. Several methods of estimating the amount of urea are in use, but the one known as the hypochlorite process is most convenient for clinical use. It depends on the fact that a solution of hypochlorite will decompose urea, and liberate its nitrogen in the free state. This nitrogen being collected and measured will, by calculation, give the amount of urea present. To save trouble, a table is supplied with the apparatus, which shows the percentage of urea, and the quantity contained in a sixteen-ounce pint, thus simplifying the calculations.

"The urine should be collected for twenty-four hours as follows: Commence at any hour by emptying the bladder and throwing the urine away. The whole urine passed during the next twenty-four hours evacuating the bladder at the same hour, should then be mixed together, measured, and a sample sent for examination, with a statement of the exact quantity of the product.

"When a fall in the excretion of urea is disturbing the system, it is well, first, to cut down the albuminoid elements of food; secondly, to increase renal excretion; thirdly, to act upon the bowels and skin. But the only way to ascertain this fall in the excretion of urea, is to test the urine in the manner described daily, or at any rate frequently, in all suspicious cases."

"Defective action of the kidneys can be compensated by rousing the skin and if the bowels, become constipated in renal inadequacy, they should be promptly acted upon. At the same time, it is well to stimulate the sudoriferous glands of the skin.

CLINICAL LECTURERS.

We have had occasion before to call attention to the dereliction of clinical teachers in coming late to their clinics and thus *forcing* the students unwillingly to lose a portion of their valuable time. Recently we attended two prominent hospitals on the same day. The first lecturer was fifteen minutes, the second ten, and the third (at the second hospital) ten minutes late, thus, in three hours, causing a loss of thirty-five minutes of valuable time to the students.

Clinical teachers should recognize that they owe a duty to the students; the advantages of clinical teaching are reciprocal, the benefit is not entirely derived by the student, for these lecturers are advertising themselves to the future physicians who will be sending their difficult cases to "city doctors," and this dereliction will cause an unconscious black mark against their names in the minds of these embryo physicians. *A word to the wise is sufficient.*

"CONSUMMATUS EST."

As we intimated in our last issue, the Board of Guardians of the Poor of this city have displaced Dr. Richardson from his position of physician-in-chief of the Insane Department of Blockley, and have elected in his stead a man without experience as an alienist.

This action can only be characterized as OUTRAGEOUS. It was the direct result of political wire-pulling, and is a disgrace to the charity of our city. It is a crying shame that our *insane paupers* should be placed at the mercy of a lot of huckstering politicians, and it looks very much as though the affairs of Blockley again required the investigating hand of the Committee of One Hundred.

We cannot recall that we have ever been called upon to record a more flagrant injustice. Dr. Richardson was eminently capable, *but he was not a politician*, and he had to go. This is the plain English of it. Let the visiting staff take note, whose turn will come next!

THE MEDICAL RECORD.

The New York *Medical Record* takes exception to our editorial in the issue of December 19, in which we speak of that journal as "the organ of the New York Circle," and denies the charge.

Without wishing to injure any one, we would merely call the attention of the *Record* and the profession to two questions, the answers to which, we feel, will sustain our position.

1. Who started the revolution against the New York County, the New York State, and The American Medical Associations, some three years ago?

2. What journal supported those who started this revolution?

There can be but one answer to these question. The revolution was started by the New York Specialists, who desired more freedom of consultation, and the revolutionists were supported by the *Medical Record*.

MUSHROOM POISONING.

Every physician should carefullly read the article on "Amanitine," by Mr. Charles McIlvaine, in two recent issues, and should store away in some handy recess of the brain the cases so well reported by Dr. Shadle.

Cases of mushroom poisoning are not very common, yet they are just the cases to which we are called at a moment's notice, and which we are obliged to treat at once. The literature of the subject is not very extensive, while the field is amply covered in the article in question.

Notes and Comments.

The Physicians' Clinical Record as a Gift!

All subscribers who remit for the full year 1886, before the 15th of January, will be entitled to a copy of the *Physicians' Clinical Record*. This is a very convenient memorandum book, adapted to contain the clinical record of one hundred cases of disease. It is neatly bound, and suitable for carrying on the person.

In all cases, the remittance must be made for the full year, and direct to this office. Subscriptions sent through agencies will not be entitled to the gift.

Hysterical Hemianæsthesia.

It is true that our text-books have comparatively little to say on this subject, and it is to be regretted, since in these days of steam, æstheticism, progress, worry, abortions, and conjugal frauds, the hysterical element, particularly in women, plays a very important role in disease. Hence is it well that we note some points from Dr. F. C. Fernald's paper in the *N. Y. Med. Jour.*, November 7. While most commonly observed in young women, this affection is not limited to any sex or age. The left side is most often affected, the anæsthesia, beginning exactly in the median line, being, in marked cases, absolute. Not only is the sense of touch gone, but also are the special senses on the affected side. The skin is paler and cooler, and bleeds but slightly, if at all, when pricked or cut. Typical cases are rare, and there may be every degree of variation. The attack may come on suddenly or gradually, and may last for days, months, or years. Its departure may also be sudden or gradual. There is also often involvement of motion.

Hysterical hemianæsthesia has one striking peculiarity in the fact that the patient is usually unaware of its existence, and that the physician himself is apt to overlook it unless he makes his examination in a thorough and methodical manner. To avoid deception, it is essential that the patient should have his eyes closed during the testing of the cutaneous sensibility, and it is best that he should also not know beforehand what is to be done. The test is made by pricking with pin, by the electric brush, by small bottles of water at different temperatures, and by other means that readily suggest themselves. The examination of the skin should be the first test in the examination of the patient, because, if any anæsthesia is found, it gives the key to the affected side, and knowing this we can avoid being deceived while testing the special senses. Always try the special senses of the suspected side first; otherwise the patient may be self-deceived by mistaking what we may call the

"after-images" of the impressions that have been made upon the well side for genuine impressions on the affected side.

Be always on your guard for malingering.

Mental and moral influences and *time* are the best *curative* agents.

A Case in which Four Tapeworms Co-existed in one Person.

Dr. T. A. Palm reports the following somewhat peculiar case in the *Lancet*, Nov. 28:

A German gentleman residing in Niigata, Japan, had suffered from tapeworm for more than twelve years, and had undergone a variety of treatment without avail, having at one time eaten a large plateful of boiled pomegranate-root. He prescribed for him eighty minims of the ethereal extract of male fern, to be taken on awakening in the morning, after fasting from noon of the previous day. It was taken in milk, in three portions, at short intervals, and the recumbent position was maintained till nausea had passed away. He had explained to him the importance of finding the head, and described what it was like. Later in the day he brought in triumph two heads in a small phial, and a large quantity of tapeworm. Upon arranging this around a large tray in lengths, he found that there was more than could be accounted for by two tapeworms, there being an array of the narrow segments near the head, beside those belonging to the two heads already evacuated. He was somewhat incredulous when informed that he had another left in him. After some weeks, however, he paid a further visit, as he was again passing proglottides. The male fern was administered as before, bringing away one head and a considerable length of the worm. Upon examining this, and carefully putting it together on a tray, he again found that there were two lengths of the narrow upper portion of the parasite, which evidently belonged to separate worms. The patient delayed treatment until there was indisputable evidence that he was not cured, and then a third dose of the same remedy brought away the fourth and last head. His health did not appear in any way to suffer from the presence of the four tapeworms. His appetite was somewhat improved by the presence of the four guests whom he entertained, but this was a symptom of which he did not complain. He sought relief from the annoying consciousness of being the victim of a repulsive parasite.

Retention of Broken Glass in the Vagina for Seven Months.

Dr. J. A. Angus thus writes in the *Brit. Med. Jour.*, November 28, 1885:

On October 19, I was called in to see Mrs. F., aged forty-seven, who informed me that about five years ago, when in London, she consulted a physician, who told her that some displacement of the womb existed; but, under the treatment adopted then, relief was soon obtained.

Menstruation having ceased for the last six months, and some slight return of the old symptoms being felt, she requested me to make the necessary examination. On introducing the forefinger of right hand into the vagina, it came upon a hard round body lying to the right and posterior side of the cervix uteri. It felt firmly fixed, but, after some patient manipulation, became dislodged, and, to my astonishment, proved to be the broad perforated end of a broken glass female syringe.

The patient was amazed, and, upon my questioning her with regard to it, said that, about seven months ago, she broke a syringe when using a vaginal injection, but, hearing her husband coming upstairs, put the fragments into the chamber utensil, and thought no more about it.

Copulation has been performed many times since then, the husband complaining of feeling some obstruction. The position of the foreign body had become exactly reversed, as the sharp point was lying upwards in the posterior vaginal wall, the convex blunt end of the syringe with its numerous perforations downwards, and, as mentioned before, being moulded to the right posterior side of the cervix. How such a sharp-pointed body became reversed and worn so long without injury to the vagina, and comparatively little discomfort, is most singular.

Iodol.

A foreign exchange says: To the progress of synthetical chemistry we owe an addition to our present list of local antiseptics which, if on further trial it be found to bear out the promises made for it by its discoverers, bids fair to take the place of iodoform altogether. Iodol, the substance referred to, is a dark powder obtained from "Dippel's animal oil." It has but little smell, and is soluble in 3 parts of absolute alcohol, but only in 5,000 parts of water. More than two hundred observations on various diseases have been made with it in the Royal Surgical Institute in Rome. It was used in sub-

stance, suspended in glycerine, dissolved in alcohol with glycerine, and as ointment. Chancres were washed with distilled water, very carefully dried, and sprinkled with iodol in powder, and covered with silk protective, the dressing being changed daily. In six days' time the base of the chancres began to granulate, and the edges to show signs of commencing cicatrization. Similar treatment was adopted in the case of open buboes, which very soon began to exhibit a healthy appearance, and in a short time healed up. In many cases of simple indolent ulcers iodol was equally valuable, the whole character of the sore becoming changed after a few applications. Neither erysipelas nor diphtheritis was ever observed in cases treated with iodol.

A Case of Poisoning by Datura Stramonium.

Dr. Roth László, in *Nagy-Bajom* (Somogy), in Ungaria, reports the following interesting case in the *Wiener Med. Blatter*, September 11, 1885:

A girl, aged four, had eaten a large quantity of the seed, flowers, and leaves of datura stramonium. The most intense symptoms of poisoning, very similar to those which, as well known, occur after intoxication by belladonna, rapidly developed themselves, and notwithstanding the immediate and liberal use of emetics and the other remedies generally employed in these cases, no improvement set in, and the prognosis appeared exceedingly grave. While examining the little patient, Dr. L. noticed the great dryness of the skin, so characteristic of poisoning by stramonium or belladonna. This fact suggested to him the administration of muriate of pilocarpia, and as the case seemed hopeless, a considerable quantity of a one per cent. solution of this drug was hypodermically applied. About one grain of the remedy—a very large dose, considering the age of the girl—was thus injected, improvement suddenly set in, and continued so rapidly that ten minutes later, after the last injection, which brought the dose of the pilocarpia up to one grain, the child had completely recovered, without leaving any trace of the poison or evincing any morbid symptom which could have been ascribed to the effect of the pilocarpia.

An Instructive Case.

How a diathesis of the blood may often give rise to obscure symptoms, which it is at times almost impossible at once to recognize as regards their true meaning, we have often shown in these pages by the report of cases. The following, published by Verneuil, in the *Gaz. Hebd.*, 1885, 31, is specially instructive:

To Dr. V. a washerwoman, æt. 31, was brought, who had a small wound made by a knife in her left breast. Twenty-four hours later an incessant cough developed, unamenable to treatment, and the patient also complained of severe pains in the region of the left hypochondrium. Revulsives and narcotics were of no avail. Then the suspicion of the presence of malarial poison in the system was awakened. Sulphate of quinia was administered, and one day later the patient was discharged cured. For nine days after this, and after the little wound had long since completely healed, the symptoms suddenly returned, and once more yielded rapidly to quinine, the cure this time proving permanent. V. had first considered the symptoms to be due to hysteria, until he heard that the patient, when 13 years old, had suffered for over a year from intermittent fever. The case was specially complicated by the remains of an old pleurisy on the same side as the wound and the pain, so that nothing appeared more plausible than to ascribe the symptoms to the affection within the chest caused by the injury, and only the want of effect of treatment induced V. to make further inquiry.

Pichi, a Chilian Remedy for Cystitis.

The *London Med. Times* says that a Chilian plant, called by the natives Pichi (*Fabiana Imbricata*), has long enjoyed a great local reputation in the treatment of urinary diseases, having even been supposed to cure renal and vesical calculi. Although, doubtless, its virtues have been exaggerated, it is believed by a writer in the *Diario Medico-Farmaceutico*, A. Rodiguez, of Buenos Ayres, to be very efficacious in certain maladies of the urinary organs and of the liver. He finds that it is especially valuable in vesical catarrh produced by the mechanical irritation of gravel, calculi, or due to a uric acid diathesis. It allays the irritation, lessens the secretion, and favors the expulsion of the gravel and of calculi which are sufficiently small to pass through the urethra. Its effect on hepatic disorders appears to be due to its climatic action. It has been found useful in Rio de Janeiro in several cases of jaundice, dropsy, and dyspepsia, due to deficient biliary secretion. A fluid extract of the plant is prepared, containing 20

grammes to each tablespoonful, and of this from four to six tablespoonfuls are given *per diem* in either hot or cold water. Dr. Demarchi has examined pichi chemically, and finds in it,

1. An essential highly aromatic oil.
2. A resin; and,
3. A fluorescent substance resembling esculin, paviin, and fraxin, which crystallizes in needles.

Injection of Defibrinated Blood Hypodermically.

Dr. Oscar Silbermann, of Breslau, has published an account of two cases of severe anæmia which he treated successfully by the subcutaneous injection of defibrinated human blood. The first case was that of a little boy of eight, who after measles and whooping-cough became very anæmic, there being a systolic mitral murmur, vomiting, and fainting fits. Iron and other drugs were tried and proved useless, so forty grammes of defibrinated human blood were injected under the skin of the thigh, and a rapid improvement resulted. The injections were therefore repeated, and the child was completely cured. The second case was that of a girl of eleven, who had been reduced to a highly anæmic condition by profuse bleeding from a rectal polypus. There were in her case, as in that of the boy, a systolic mitral murmur, vomiting, and fainting fits. Fifty grammes of defibrinated human blood were injected subcutaneously into the thigh, and rapidly brought about a cure. The author remarks that the greatest care must be taken to disinfect the hands, the instrument, and the cutaneous surface, both of the patient and of the person who gives the blood. The blood must be completely defibrinated, and kept at a temperature of 39° C.; also, during and after the injection, the surface should be rubbed or stroked in an upward direction.

Hypodermic Injections of Salicylate of Cocaine in Neuralgia.

The *Lancet*, Oct. 17, says that Dr. Max Schneider has seccessfully employed subcutaneous injections of 0.4 gramme (about a quarter of a grain) of salicylate of cocaine in the case of a woman suffering from a third attack of severe neuralgia affecting the second and third divisions of the fifth nerve. Her first attack, which occurred five years previously, had been cured by large doses of quinine. The second attack lasted for nearly six months, and was quite unaffected by quinine, but ultimately yielded to morphia and iron. The third attack had already lasted for four weeks, when the author commenced the use of the cocaine. He injected it into the right cheek eight times in six days, the punctures giving no pain, and being followed by no unpleasant effect. This was followed up by the employment of the constant current, the anode being applied to the painful spots, which corresponded with the points of exit of the branches of the nerve, and the cathode to the neck. The relief from pain and from the consequent insomnia afforded by the cocaine was remarkable, and Dr. Max Schneider thinks that this method of relieving neuralgia is well worth further trial.

Theine.

After writing on the analgesic qualities of this drug, in the *Med. News*, December 12, Dr. Thomas J. Mays thus concludes:

"From the results of the action of theine in these cases, it will be seen that it is a powerful anodyne without producing any intoxication of the higher nerve centres, which is so common with morphia and all other agents belonging to this class. Its influence is both quick and persistent, and it manifests an almost exclusive affinity for the sensory nerves. It relieves pain by acting from the centre toward the periphery, and showing its effects but very seldom above the seat of injection. This is precisely in harmony with what was found in the experiments on the lower animals. In $\frac{1}{10}$, $\frac{1}{5}$, and even $\frac{1}{3}$ grain doses it is entirely free from dangerous consequences—the only inconvenience which it causes is a slight, but transient burning at the point of introduction. I use a one per cent. watery solution of Merck's preparation—ten minims of which equal one-fifth of a grain of theine. Larger doses are required in some individuals in order to bring out its characteristic action."

Comparison of Packing and Hot Baths in the Treatment of Nephritis.

A considerable number of observations have been made by Dr. Gess, of St. Petersburg, with the object of determining the relative effects of wet-packing and hot-air and hot-water baths as diaphoretic agents in the treatment of nephritis. He finds that the temperature is raised by all these methods of treatment, the greatest elevation being produced by the hot-water baths, and the least by the packs. The effect of the

packs, too, is the more transient, as twenty minutes afterwards the temperature falls, whereas it remains high for fully an hour after the hot-water baths. The same difference is observed in the increase of the pulse and respiration by the three methods of treatment. The diaphoretic action appeared to follow the same law, being greatest after hot-water baths and least after packing; the effects of the hot-air baths appearing, as in the foregoing cases, to be intermediate between the hot-water baths and the packs. He therefore thinks that hot-water baths offer a mode of treatment preferable to the others.

Recovery of Speech.

In the *Epworth Bells* of October 31, a remarkable case is recorded in which an old man of seventy-three years of age, who had been dumb since he was fifty-three years old, suddenly recovered his speech. Although about the same time that speech was lost he also became deaf, it is quite obvious that he did not become dumb in consequence of loss of hearing; for although after adult life has been reached, in those cases where hearing is completely and suddenly lost, the voice undergoes considerable alteration in tone, the power of modulating it being absent, the ability to speak in the language that has been acquired remains. This is, of course, quite a different state of things from what happens in early life, where words which are not constantly heard are very rapidly forgotten. When the loss of speech in children succeeds deafness, the loss is gradual; but in this instance of the old man, both the loss of speech and its recovery were equally sudden, thus pointing to an intracranial lesion, and not depending on the deafness.

Lagophthalmos in Diabetes.

Facial paralysis has not had much attention drawn to it in diabetics. Dr. Fieuzal, in the *Bulletin de la Clinique National Ophthalmologique de l'Hospice des Quinze Vingts*, of September, 1885, relates three cases of the facial paralysis under the title of "paralytic lagophthalmos in diabetes." The first case was that of a man in whom the right side of the face became paralyzed suddenly; corneal ulcers developed; the duration of the paralysis was three months, and ended in complete recovery. A year later the left side of the face was paralyzed for four months. There was no history or evidence of syphilis, and none of rheumatism, but the urine was loaded with sugar. The treatment was simply that used for diabetes, together with some galvanic stimulation of the muscles. The history of the other two cases was practically of the same kind as the one we have briefly sketched.

Correspondence.

BERLIN CORRESPONDENCE.

Ichthyol and its Uses.

Eds. Med. and Surg. Reporter:

Ichthyol, in the opinion of Dr. Lorenz, who speaks from experience, is an admirable, in some points unequalled remedy against inflammation; for on the one hand its effects are quicker than other remedies, and besides it can be used, especially in war, on the upper parts of the body without disabling the patient. Dr. Lorenz gives a few cases in which he has proved its efficiency as follows:

Mrs. M., 63 years old suffered for ten years from irritation and burning of the entire skin; she states that this had been the case even in childhood, but only for the last ten years had it been so unbearable that for weeks she was unable to sleep—patient said she had been treated unsuccessfully by four physicians. Dr. Lorenz, on examination, found the picture of prurigo—the recipes shown to him proved that all the remedies generally used had been prescribed; he therefore tried ichthyol (recommended by Dr. von Hebra) with water (30:100). On the following day the patient, who, after a warm bath, had used it twice, declared that she felt only slight irritation, and was able to sleep. She used it two weeks longer, and up to the present, although three months have passed, has felt no irritation.

In pruritus, especially in obstinate cases of vulvitis and pruritus, a solution of ichthyol and water has also done splendid service. In burns it has proved efficient, almost instantaneously relieving the pain, and, when used immediately, preventing the formation of blisters.

Patient 53 years old had severely burnt his right hand; the entire back of the hand was a granulating ulcer, the fingers and back of the forearm covered with blisters. After opening and partially emptying them a 10% watery solution of ichthyol was poured over the hand, and a linen bandage soaked in oil enwrapped it. The healing was remarkably quick.

Dr. Lorenz has tried the 10% solution in

cases of badly healing sores and ulcers of the anus, and has always found it excellent.

Internally the Doctor has used ichthyol chiefly in chronic cases of catarrh of the stomach, and its taste not being agreeable, although not so disagreeable as chinin, for example, the Doctor gives it to females in capsules; males have no difficulty in taking the one per cent. solution (4 to 6 tablespoonfuls pro die).

Patient M. had suffered several years with catarrh of the stomach; had been troubled by vomitus, not only in the morning but also afternoon. Bism. subnitr., with morphine, gave partial relief during severe attacks; other remedies had failed in giving even relief, not to mention cure.

Dr. Lorenz tried ichthyol-natron capsules (à 0.25 grammes). After sixteen capsules had been taken the vomitus had ceased; patient felt himself in excellent health, with strong appetite, which had previously been very weak.

The New Hygienic Institute in Berlin.

In the beginning of December Professor Koch had his first lecture in the lecture hall of the Hygienic Institute. The audience was composed of many students, younger and older physicians, some pupils of Koch, Dr. Frobenius, of Munich, and several foreign physicians from Spain, Italy, France, etc., all eagerly waiting to greet the new professor.

Prof. Koch, who is gifted with a sonorous, agreeable voice, commenced in a simple and clear manner by a historical review of the development and importance of hygiene, as being that science which seeks to preserve health.

While physicians have been learning to cure diseases, they are now learning how to prevent them. The first instigation to this rational view of the cultivation of health, was given by the cholera epidemic of 1830, which showed the helplessness of the physicians. It was only afterwards that the high sanitary worth of cleanliness, good drainage, etc.. began to be understood. In the opinion of the lecturer, Pettenkofer, of Munich, was the first founder of exact scientific hygiene. He first pointed out the dependence of cholera to the soil, was the first to begin experimental researches on the causes of diseases, and in the Hygienic Institute of Munich gave the first instruction in hygiene. Since then hygienic institutes have been added to other universities, to the University of Berlin among others, and it is creditable to the present Minister, that in spite of many obstacles, he has done justice to the claims of science.

Prof. Koch then spoke of the efficiency and capability of hygiene as illustrated, for example, in vaccination, cholera-prophylaxis, etc. The high value which England, for example, gives to the rational cultivation of health is shown hereby, that more than £27,000,000 are annually given to hygienic purposes. This sum appears enormous, but more than its equivalent is reached by so many lives being preserved, and so many causes of disease being removed.

In his next lecture Prof. Koch will speak on the "Special Aims of Hygiene."

Berlin, 6, 12, '85. Dr. L. Casper.

News and Miscellany.

NOTES ON MEDICO-LEGAL MATTERS.

BY HENRY A. RILEY, ESQ., NEW YORK.

Adulteration of Food Products.

The subject of the adulteration of food products is rapidly acquiring a prominent place among economic questions, and more stringent laws are urged. In the case of oleomargarine, however, the most stringent laws have been declared in New York by the Court of Appeals to be unconstitutional. The law was absolutely prohibitory there, and was vigorously carried out until the highest court in the State decided that the manufacture and sale of oleomargarine could not be prohibited, as when properly prepared it was not unhealthy. This position must be accepted as sound, but in effect it permits the sale of oleomargarine for genuine butter, as imitation butter is never sold for what it really is, but always for the genuine article.

In Pennsylvania a test case is pending, and a decision similar to that in New York is very likely to be rendered. The manufacture of oleomargarine is assuming gigantic proportions, and at the recent National Butter, Cheese, and Egg Convention, held at Chicago, this was the principal topic of discussion. Most of the speakers thought that the only remedy was in a uniform law to be enacted by Congress.

A Curious Bastardy Case.

A curious case in medical jurisprudence occurred recently in Wisconsin in a bastardy case. The design of the prosecution was to

prove that a certain person was the father of the bastard child and liable for its support. With this view, the child was offered in evidence, with the intention of showing the personal likeness between the two. This was objected to, and the general question considered of the propriety of such evidence, with the result that the child was excluded from the witness-box. The court quoted with approval the following opinion from Beck's "Medical Jurisprudence:" "It has been suggested that the resemblance of a child to the supposed father might aid in deciding doubtful cases. This, however, is a very uncertain source of reliance. We daily observe the most striking differences in physical traits between parent and child, while individuals born in different parts of the globe have been mistaken for each other. And even as to malformations, although some remarkable resemblances in this respect have been noticed between father and child, yet we should act unwisely in relying too much on them. There is, however, a circumstance connected with this, which, when present, should certainly defeat the presumption that the husband or paramour is the father of the child, and that is when the appearance of the child evidently proves that its father must have been of a different race from the husband or paramour, as when a mulatto is born of a white woman whose husband is also white, or of a black woman whose husband is a negro."

—

Testimony in Insanity Cases.

A recent case in Pennsylvania states some rules as to testimony in insanity cases which will be of interest. Witnesses by general study and experience may acquire such skill as will qualify them to give an opinion as experts in matters relating to insanity. Witnesses may also possess such special knowledge of a particular person as to qualify them, though not properly experts, to express an opinion as to that person's mental unsoundness; such an opinion, however, must be based upon facts testified to.

Witnesses not shown to be experts and not having testified to facts tending to show mental unsoundness, are not competent to express an opinion in regard thereto. The facts which they have testified to need not, however, be excluded. The burden of proof of insanity is upon the party alleging it, and may be supported by proof of a general mental unsoundness during a prolonged period, or of a particular unsoundness at a precise period; if the proof shows a general mental unsoundness during a prolonged period, the burden of proof is shifted upon the other party to show that any act in such period was performed during a lucid interval.

—

Compulsory Vaccination.

The question of compulsory vaccination was discussed at a recent meeting of the Society of Medical Jurisprudence in New York, and the general opinion was expressed that a law would be desirable which should make vaccination a necessity. It was not thought, however, that the adoption of such a law would be politic now, before the community had been educated up to stronger belief in the efficacy of vaccination.

Dr. Taylor, of the Board of Health, gave some statistics which showed that the opposition among people living in the poorer districts was very much less than it formerly was.

—

The Treatment of Hysteria.

A prominent physician of Paterson, N. J., was arrested a short time since under very curious and amusing circumstances. The physician was summoned to attend a person who was said to be suffering from cramps, and the following is the statement made subsequently to the Police Justice by the patient of the treatment he received: "When the doctor arrived, I was on the lounge in great misery. He felt my pulse, and then began to cuff me, first on one side of the head and then on the other. Then he hit me in the eye and knocked me off the lounge and wiped the floor with me. I want him arrested."

"Perhaps it was some sort of treatment the doctor was giving you," suggested Recorder Greaves.

"What! knock a man on the head and hit him in the eye for a pain at the pit of the stomach? No, I guess not! I want him arrested."

The warrant was, after a while, issued, and the doctor, in his turn, made a statement of the affair: "Why," said he, "I found the man suffering from hysteria. His pulse and condition showed that he really had no such cramps as he described. No doubt he thought he had, but it was a purely nervous trouble. I tried to engage his thoughts and get them off the apparent seat of pain, but being unable to do so in any other way, I had recourse to the old-fashioned method of making him angry; I slapped his cheeks and rubbed his ears. As soon as he got angry he experienced a change of the current of his thought, and the attack of hysterics was

over. That ended the pain. That is a frequent remedy in a hypochondriacal attack."

What the result of the arrest was does not appear, but the physician was probably discharged.

The Medical Staff in Germany.

Our Berlin correspondent writes that the general increase of members of the learned professions is also noticeable in the medical profession. In 1866 Prussia contained 7,846 physicians; in 1876 there were 8,161; in 1878 8,372; in 1881, 8,439; in 1882, 8,553; in 1883, 8,693; in 1884, 8,808, and in 1885, 9,018, an increase in one year of 210, or 2.7 per cent.

The increased number of medical students at the German universities portends a still greater additional growth of the medical profession for the future. The distribution of physicians throughout the kingdom is unequal. Apart from the city district, Berlin, which has 1056 physicians, the gubernatorial districts of Dusseldorf and Breslau contain the largest number of medical men, these having 543 and 528 respectively; then come Weisbaden with 431, Schleswig with 399, Potsdam with 392, and Cologne with 382, whilst Stralsund contains but 95, Cöslin 90, Aurich 85, and Stade 82. The greatest increase since last year, an addition of 54 (5.4 per cent.) falls to Berlin, next comes Breslau, with additional 14 medical men, Oppeln 12, Dusseldorf 11, Liegnitz 10, Königsburg also 10. The districts Posen, Stade, Coblenz, Osnabruck, and Schleswig have fewer physicians than last year. The decrease was greatest (7) in Schleswig. Comparing the number of physicians with the number of the population according to the census of 1880, we find 3,025 inhabitants for every one medical man; but assuming, according to the latest information of the Royal Statistical Bureau, the present population of Prussia to be at least 28,750,000, there would be one physician for every 3,188 inhabitants. In the several districts the number of inhabitants to one physician is very different. On an average there are far fewer medical men in the eastern parts of the kingdom than in the western. In Wiesbaden there is one physician to 1,700 inhabitants, in Cologne one to 1,892, in Bromberg the rate is one to 5,678, Oppeln one to 5,748, Marienwerder 6,108, Cöslin 6,512, and Gumbinnen one for 7,413 inhabitants. Among cities, apart from Berlin, which contains 1,056 physicians, Breslau has the largest number, 258—the same number as last year—then follows Cologne with 148, Königsberg with 137, Frankfort-on-the-Main with 124, Hannover with 194, Weisbaden with 90, Bonn with 71, and Danzig with 70. In comparison with the number of inhabitants, the university towns, the watering places, and then those cities whose population numbers above 100,000. have the largest number of physicians. In Bonn, there are but 440 inhabitants to one physician. in Wiesbaden 558, in Cologne 970, and in Berlin 1,063. In the smaller towns the number of physicians diminishes, and there are in Prussia 72 towns, or market places, which contain neither physician nor apothecary, 19 which contain one and even two physicians, and 15 which boast of an apothecary but no physician. Comparing the proportion of physicians with the area of the empire, we find one physician to 38.8 square kilometres; in the gubernatorial district Gumbinnen the rate is 1 to 151.1 square kilometres, and in the gubernatorial district Dusseldorf one to 10.1 square kilometres. The oldest physician in Prussia, Dr. Schlegel, of Liegnitz, who passed his examination in 1814, died this year. At present, Dr. August Zeider, of Reichenbach, O. L., who passed his examination in 1819, is probably the Nestor among Prussian physicians. The oldest physician of Berlin is Dr. Steinthal, who passed his examination in 1821, not 1823, as falsely stated in the "Medical Almanac." Last year 226 physicians died, almost 3 per cent. of the entire number. In the previous years the number of deaths had been but 213 and 182. In all these calculations the surgeons second class have been included; their number is not large, only 72 all told; of these, the gubernatorial district Merseburg has the greater number, namely, 16. In 13 gubernatorial districts not one surgeon second class can be found.

Among the medical officers, we mention only the "Kreisphysici" and "Kreiswundarzte." In all Prussia there are 474 "Kreisphysikate" and 429 "Kreiswundarzte."

In the medical faculty of the nine Prussian State Universities there ate 87 professors in ordinary and 95 (last year 99) professors extraordinary, besides 124 (117) "privat docents."

The number of dentists, which probably owing to the competition of their American colleagues had fallen, has been rising considerably during the last few years. In 1883, 247 were counted; in 1884, 265; in 1885, 278; in two years an increase of more than 12 per cent. Berlin alone has 67 den-

tists, more than 24 per cent. of the entire number; the gubernatorial districts, Schleswig with 24, Dusseldorf with 21, and Wiesbaden with 18, show a strong conflux, against which throughout the entire gubernatorial district Marienwerder not a single dentist is to be found.

With regard to apothecaries, there are now 2,494. Since 1879 only 65 have been opened—0.4 per cent., not quite 11 to one year. In 1866 the rate was 1 apothecary to 3.55 physicians, now to 3.61. Whilst there is on an average in the entire State 1 apothecary for every 10,937 inhabitants, the rate is in the gubernatorial district Aurich 1 for 5,427, in Osnabruck 1 for 6,290, and in Stade 1 for 6,710; but in Cöslin the rate is 1 for 17,213, in Oppeln 1 for 17,999. In Berlin 9 new apothecaries have been opened, in Schleswig 5, in Potsdam 3. In Hanover only there has been a decrease of 1. The number of military physicians has also increased. It is well known that for years the military authorities found great difficulty in keeping the number of active sanitary officers up to the required standard, but of late the number is constantly rising. In 1883 there were 985; in 1884, 999; and at present there are 1,021.

Professor von Bergmann.

Our Berlin correspondent writes us that Prof. von Bergmann, the director of the Surgical Hospital of Berlin, recently celebrated the 25th anniversary of his career as a surgeon. Born in Finland, he passed his examination at the University in Dorpat. His education was the usual one of surgeons. Following his academical studies, he traveled a while, stopping longer in Berlin and Vienna. He then began practically, as assistant at the Surgical Hospital in Dorpat, under direction of Prof. von Adelmann. But it was the wars of the years '60 and '70 which considerably furthered him in his surgical skill. In 1866 Bergmann was employed in the Prussian service in the war hospital at Königshof, Bohemia, and during the war with France he was chief surgeon in the barracks of Karlsruhe and Mannheim; in 1877 he went into the field with the Russian army of the Danube as consulting physician.

Bergmann has given his experience of battle surgery in a series of writings. He has specially contributed articles on Excision of Joints. This operation on the knee was first brought into more general practice in war surgery by Langenbeck and Stromeyer during the Schleswig-Holstein war of 1851. It was in the Russian-Turkish war that Bergmann first tried the antiseptic bandage of Lister, which had previously not been used in war surgery. Besides the writings founded upon his practice and surgical experience, Bergmann has written a series of purely theoretical investigations, which are principally a continuation of Lister's inquiries into antisepsis. These articles were begun during the year of '60, and have not yet been concluded.

With regard to "Septische Intoxication" wound fever, Bergmann believes it to be caused by "sepsin," an organic azotic body which he has found in decayed yeast, and which, when introduced into the organism of an an animal calls forth the symptoms of septical infection. Later experiments of Schmiedeberg and O. Angurer in Würzburg, are calculated to confirm Bergmann's theory. To complete the picture of Bergmann's literary work, we must mention his works on "Kopfverletzungen" which appeared in the *Deutsche Chirurgie* of 1880, also his "Krankheiten der lymphdrüsen" in Gerhardt's "Handbuch der Kinderkrankheiten."

Very original was his first larger work, entitled "Die Lepra in Lirland," which was published in 1867. Leprosy, as an epidemic, is met with in Europe only in Norway and Sweden, and far more seldom in the east sea provinces. In his book Bergmann makes known all that he has ascertained about leprosy in his native country.

Bergmann remained in Dorpat until 1878. He then went to Würzburg as the substitute of Linhardt. In 1882 he settled in Berlin as director of the University Hospital, succeeding Bernhard von Langenbeck. Here he had to battle with many difficulties. His lectures on surgery are listened to with intense earnestness by the students, who, term after term, crowd his lecture hall to the doors.

Remarkable Italian Fecundity

Expressing considerable doubt as to its veracity, we note as follows from the Naples letter to the *Paris Register:*

"The most extraordinary case of fecundity that I have ever heard of came to my knowledge last week. About twenty-five miles from here, and by rail two or three stations beyond Pompeii, is the historical city of Nocera (the Nucera of the ancients). In the rione, or ward, of Liposta lives Maddalena Granata, aged 47, who was married at the

age of 28 to a peasant, just nineteen years ago. Maddalena Granata has given birth to, either dead or living, fifty-two children, forty-nine of whom were males. She enjoys florid health, is robust, and twenty-four hours after her last accouchement was ready to go out to her accustomed labor in the field. She has no hesitancy in conversing with any one about her extraordinary prolificness. Her physician, Dr. Raphael de Sanctis, of Nocera, says that there is not the least exaggeration in these statements. Has any one ever heard of such phenomenal fecundity in the whole history of maternity—fifty-two children, alive or dead, in nineteen years! She has had triplets fifteen times."

History of the Pennsylvania Hospital.

There is in existence a valuable history of the Pennsylvania Hospital, written by Franklin himself, in which he gives the credit for originating the enterprise to his friend Dr. Thomas Bond; but great as were the services of this active physician in the movement—he and his brother and Dr. Lloyd Zachary, when the cost of medical attention became a barrier, offering to serve gratuitously for three years, and thereby setting the precedent that has ever since been followed—it is evidently and fully attested by records and other evidence that Franklin was the prime mover throughout. He kept in the background partly from his modesty, but principally because he was at time a candidate for Representative of Philadelphia in the Assembly. Even at this time Franklin had the idea of national independence on his mind, and of his wonderful foresightedness and longheadedness nothing can give better evidence than the fact that the present great hospital building is just as he planned it a hundred and thirty-five years ago, though the population of the city, then 20,000, has grown to nearly a million. He was building for the future.

Items.

—It is estimated that there are now in the United States 120,000 practitioners of medicine, including non-graduates.

—"Charlatanism," says Dr. Holmes, "always hobbles on two crutches—the tattle of women and the certificates of clergymen."

—Dr. Edson, of the New York Health Department, recently seized, at the West Washington Market, the carcasses of eighteen hogs which had died of hog-cholera.

—The *Med. Record* of December 26 says that it is reported that the New York Post-Graduate Medical School will not receive medical women as matriculants after the present session.

Personal.

—Dr. and Mrs. Fenton have arrived out on their way to Germany.

—George Alfred Townsend visited Northumberland borough several days ago to gather information of Dr. Priestley, the famous philosopher and discoverer of oxygen, who died there eighty-one years ago. He said he had in view a literary purpose, a book involving to some extent the life, character, and achievements of Priestley.

OBITUARY NOTICE.

JOSHUA H. WORTHINGTON, M. D.

Joshua Husband Worthington, M. D., died December 26, at his home on East Penn street, Germantown. He was born 69 years ago in Harford county, Maryland, and educated in the Jefferson Medical College, from which he graduated in 1838. He practiced four years in his native place and then came to this city. In 1860 he married Mary W. Kimber, of this city, and after her death, Sarah, daughter of Stacy B. Collins, of New York. He was resident physician and superintendent of the Friends' Asylum, Frankford; a member of the Association of Medical Superintendents of American Institutions for the Insane; American Medical Association; vice-president of the State Medical Society, and a member of the Society of Friends, and was the author of several articles on insanity.

QUERIES AND REPLIES.

Permanganate of Potassium.

Eds. Med. and Surg. Reporter:

In the issue of your journal for December 19, 1885, "Subscriber" asks for information regarding the best vehicle for the administration of permanganate of potassium. As the drug depends for its therapeutic effect upon its contained oxygen, and as the salt is so readily decomposed, yielding up its oxygen to any organic matter present, it is absolutely necessary that great care be used in selecting a vehicle for its administration. I have obtained the best results by using no vehicle at all, administering the drug in compressed tablets; if for any reason a liquid preparation should be desired, *pure* water is the only menstruum that should be used, and the solution should be freshly prepared. I may add that Dr. P. M. Deas, in the *Brit. Med Jour.*, April, 1885, p. 778, says that the best excipient in making pills is kaolin ointment, and adds that all saccharine ingredients should be carefully avoided, as being liable to cause decomposition, or even spontaneous combustion. In the same publication, page 876, Dr. Brampton states that unguentum resinæ is a more convenient and suitable excipient, as kaolin is difficult to manipulate.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also affirmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Original Department.

Lecture.

LECTURES ON INSANITY.

DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA.

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Lecture VII.

Important Medico-Legal Questions Connected with the Insane—Certification.

Gentlemen: I shall step aside from our regular course for a few lectures to discuss some of the legal relations of the subject of insanity, which interest us as physicians. Although, at first sight, it might seem that matters of this kind would be of interest only to those who intend to become medical experts, this is a mistake. Some of the finer questions, some of those which involve the more intricate problems which come before the courts, will, of course, only claim the attention of professed medical experts in insanity; but a number of other practical matters pertaining to the legal relations of this subject may at some time come before any of you.

It is my intention to make these lectures to a certain extent, or, at least, a portion of them, practically of a clinical nature. I can not bring patients before you, but I shall refer to cases which have come before me in some way, or with which I have been either directly or indirectly connected during the last few years.

In looking over my notes to plan the lectures and to obtain illustrations for them, I find that the most important questions which have presented themselves to me, and which may come before you, have been the following:

1. Questions as to placing a person in an asylum or insane hospital, or under interdiction. Under this head will be considered: *a.* Certification. *b.* Commissions or inquisitions. *c.* The procedure by which an individual can voluntarily place himself in an asylum or hospital, or under restraint. *d.* Orders of court.

2. Questions as to the release or discharge of the insane or alleged insane. Under this head will come such subjects as: *a.* Traverse of an inquisition in lunacy. *b.* Writ of habeas corpus. *c.* Discharge by order of Lunacy Committee. *d.* Discharge by order of court, as in the case of criminals.

3. The dangers of physicians in connection with cases of insanity, as from suits for malpractice, for perjury, for false imprisonment; criminal and civil suits for damages, in cases in which physicians have made affidavits, or have otherwise been interested in putting a person under restraint.

4. The validity of contracts made by insane persons, as, marriage contracts, business contracts, etc.

5. Questions pertaining to wills and to the testamentary capacity of the insane.

6. The plea of insanity in criminal cases, as in homicide, incendiarism, theft, ravishing, sexual crimes, alcoholism, epilepsy, automatism, and somnambulism.

In the first place, then, the decision as

whether or not a person should be placed in an asylum or hospital is one of great interest to all of you, since most certificates of insanity must necessarily — as experts, or so-called experts, are not scattered over the country—be signed by the general practitioner. It may be thought a very simple matter to sign a certificate. It is, so far as the mere mechanical act is concerned, but nothing connected with the certification of the insane is trivial so far as the possible consequences are concerned. The laws of different countries, and the laws of different States in this country, differ somewhat in reference to this question of certification. It would be an unprofitable task to take the time to go over with you the laws of the different States. Most of my remarks will be based on the law as administered in Pennsylvania. You will find in the very valuable work compiled by Mr. George L. Harrison,* who died but a short time ago, and who did much for the insane and the subject of lunacy, the laws not only of every State in the United States, but also abstracts of the laws of many foreign countries.

While in many states the laws appear to agree, yet they present points of difference which must be understood if you do not wish to get into trouble. In some states, for example, two physicians are required to sign the certificate in order that an individual may be placed in an asylum. In other states only one physician is required. In the State of Pennsylvania two physicians must make affidavit to the insanity. In the State of New Jersey only one affidavit is required. In Maryland also, I believe that only one is necessary. Even where one or two physicians are specified, there are sometimes other special features which must be understood. Therefore, I would advise each one to study the laws of the state in which he settles. Ignorance of the law in this, as in other matters, is no excuse, should the case go to court in a suit of any kind. I would also advise you always to study carefully the most recent enactments. For instance, the lunacy law now in action in this state is the law of 1883. It has been in operation since September, 1884, yet I find that in this city seven out of ten physicians are unfamiliar even with the special provisions for certification of insane patients as given in the new law. Several of the late works on insanity print as an appendix the laws of Pennsylvania on this subject, but these are the old laws, and if you were to rely on these text-books, you might find yourself wanting.

Let me read you one of the provisions of the new lunacy law of Pennsylvania:

"No person shall be received as a patient for treatment or for detention in any house or place where more than one insane person is detained, or in any house or place where one or more insane persons are detained for compensation, without a certificate signed by at least two physicians resident in this Commonwealth, who have been actually in the practice of medicine for at least five years, both of whom shall certify that they have examined separately the person alleged to be insane, and after such an examination had, do verily believe that the person is insane, and that the disease is of a character which, in their opinion, requires that the person should be placed in a hospital or other establishment where the insane are detained for care and treatment, and that they are not related by blood or marriage to the person alleged to be insane, nor in any way connected as a medical attendant or otherwise with the hospital or other establishment in which it is proposed to place such person.

"The certificate above provided for shall have been made within one week of the examination of the patient, and within two weeks of the time of the admission of the patient, and shall be duly sworn to or affirmed before a judge or magistrate of this Commonwealth, and of the county where such person has been examined, who shall certify to the genuineness of the signatures, and to the standing and good repute of the signers. And any person falsely certifying as aforesaid shall be guilty of a misdemeanor, and also liable civilly to the party aggrieved."

These are the exact words of the two sections of the new law relating to this matter. Now, let me read the law which was in effect until two years ago, and you can note the differences:

"Insane persons may be placed in a hospital for the insane by their legal guardians, or by their relatives and friends in case they have no guardians, but never without the certificate of two or more reputable physicians, after a personal examination, made within one week of the date thereof, and this certificate to be duly acknowledged and sworn to or affirmed before some magistrate or judicial officer, who shall certify to the genuineness of the signatures and to the respectability of the signers."*

* Legislation on Insanity, by George L. Harrison, LL. D. Privately printed. Philadelphia, 1881.

* Act April 20, 1869, section 1, P. L. 78.

The signatures of two physicians are required by both the old and the new law. The first point of difference is that, under the new law, the physicians must actually have been in practice five years. This provision has been violated several times. If the physicians at the hospital should learn that the law had been violated in this respect, they would refuse to receive the patient. This violation occurred oftener before the different institutions had distributed printed blanks with the requirements of the law printed upon them.

Another point of difference, and a provision frequently violated, is that no physician shall make affidavit to the insanity of a person in this State, unless after *separate* examinations have been made by the physicians. The tendency is to just the opposite course of action. The physician who has charge of the case will have seen the patient often, and will then call in consultation a physician specially interested in this subject, to decide about the certificate. The law is violated if the physicians make the examination together, or rather if all the examinations are made together. The provisions of the law are carried out if a single separate visit or examination is made by the physician called in to make the second party in the affidavit. This should always be done.

I do not recall a law-suit in this country where the question of separate examinations came up, but in the famous "Mrs. Weldon case" in England, which was tried within a year or two, this point helped to decide the verdict for large damages in favor of the plaintiff. This Mrs. Weldon by some is considered insane, while others hold that she is sane. She had been placed in a private asylum. She has had a number of suits, and, I believe, has gained them all. She has won large damages against a musical composer among others. It was proved that the physicians had examined her together, and there was no evidence that they had made separate examinations. So far as I know, in this country a judicial decision has never been rendered as to what constitutes a separate examination. I believe that the law would sustain the position that if the physicians made the examinations separately, *i. e.*, were not together at the same time in the presence of the patient, the examination should be regarded as separate. The law does not detail in definite terms exactly what is meant. In order to be safe, you should at least make your examination of the patient in such a way that both physicians are not in the room at the same time. It is still better, when it is feasible, to examine at separate hours, or on separate days. In regard to separate examinations, if the examinations can be made in consultation and also separately, it is certainly a good provision. It assists in providing against the possibility of two individuals actuated by bad motives getting together to put a person in durance.

The question as to the judicial officer before whom the affidavit is to be signed, is sometimes of importance. The new Pennsylvania law says, "before a judge or magistrate of this Commonwealth, and of the county where such person has been examined." An affidavit made before a notary public is of no value for this purpose in Pennsylvania. It must be made before a magistrate, or before a judge of the court. About the time this law went into effect, two physicians made an affidavit of the insanity of a patient before a notary public, and the patient was taken to Norristown, but could not be detained, and considerable inconvenience resulted.

So far as the clause in regard to relationship by blood or marriage is concerned, this holds good in nearly all laws relating to certification in all states and countries, yet physicians occasionally overlook the restriction. I know of one case in which a physician carelessly, but innocently, allowed his name to be used in connection with a patient who was sent to an insane asylum. The patient was related to him, although not closely. The object of this provision, as you can see, is to protect the individual against confinement from mercenary motives.

The last provision of the first section, with reference to the certification of the insane in this State, is that those signing the certificate or making the affidavit shall not in any way be connected "as a medical attendant or otherwise with the hospital or other establishment in which it is proposed to place such person."

This provision, like many more in the new Pennsylvania lunacy law, is copied from or based upon certain similar statutes in comparatively recent English legislation upon the subject of lunacy. One of its objects is to guard the individual alleged to be insane from the possibility of being incarcerated in an institution for mercenary or other improper motives. The proprietors of private institutions for the insane, for example, might, if this law were not in force, cause patients to be placed in institutions in which they were pecuniarily interested, directly or otherwise. This is a very proper provision—an important safeguard.

In Philadelphia, however, certain curious questions have arisen with reference to the interpretation of this provision, both in connection with the Pennsylvania Hospital and the Philadelphia Almshouse. The Pennsylvania Hospital for the Insane is under the same board of managers as the old Pennsylvania Hospital. The institution for the insane is located, as is well known, in West Philadelphia, some miles distant from the general hospital at Eighth and Spruce streets. So far as the practical working of the two institutions is concerned, they are separate institutions—that is, in the executive management, in the care of patients, in the matter of admissions and discharges, in the physicians attending, etc. They are, nevertheless, under the same jurisdiction, and the question has arisen whether or not the physicians and surgeons, on the staff of the Pennsylvania Hospital proper, can make affidavit in the case of an insane patient who is to be sent to the Pennsylvania Hospital for the Insane. So far as I am aware, no legal decision has been rendered with reference to this matter in the case of the Pennsylvania Hospital. Some of the physicians and surgeons of the Pennsylvania Hospital, however, as I happen to know, are unwilling to sign certificates because of this restriction.

The Philadelphia Almshouse is an institution of several departments. It is, however, under one general board of management, viz., the Board of Guardians of the Poor. It is divided into (1) a Hospital department, commonly known as the Philadelphia Hospital; (2) a department of Out-wards where the indigent poor who are not sick (or who are supposed not to be sick enough to demand medical care and treatment) are kept; and (3) a department for the Insane, known as the "Insane Department of the Philadelphia Hospital." The Philadelphia Hospital always contains a very large number of patients, many of whom are constantly oscillating between mental health and disease. It is therefore frequently necessary to transfer patients from the hospital to the insane department. Before the present law became operative, the visiting medical staff and the resident physicians could, without question, sign certificates and make affidavits to bring about this transfer. Since the law has been in action, the question has arisen, whether or not, under it, the medical staff, either visiting or resident, can legally do this. The matter has twice been referred to City Solicitors of Philadelphia, and both, I am told, have given the opinion that the visiting physicians of the hospital department, if not directly connected with the insane department as consultants, are competent to go upon such certificates. It is, however, held otherwise by some entitled to opinion in the matter—by the Committee on Lunacy of the State Board of Charities, or, at least, by some of its members, for instance. Some members of the Board of Guardians, and some of the physicians and surgeons, have doubted the propriety of this procedure. For a time, the medical staff, acting under a resolution of one of the committees of the Board, did not certify patients to the insane department, two physicians unconnected with the hospital being employed and paid small fees for this purpose. Recently, however, the visiting physicians and surgeons—with the exception of Dr. Wood and myself, who in addition to our positions on the hospital staff are connected as consultants with the insane department—have been certifying to the insanity of the hospital patients sent to the insane department.

That this question may give rise to trouble is not improbable; in fact, I have heard of one case in which a relative of a patient so transferred made particular inquiries with reference to those who had gone on the certificate, with the view if possible of giving trouble. This is a matter of importance with reference to the Pennsylvania Hospital and the Philadelphia Hospital, and also other institutions in similar position. It should be settled finally by judicial decision. It could be brought before the courts by a feigned issue or other process.

The new lunacy law of Pennsylvania also provides that, "No person alleged to be insane shall be received into any house for treatment or for detention unless at the time of such reception the person or persons at whose instances the person is received shall, by a writing signed, state that the person has been removed and is to be detained at his or her request, under the belief that such detention is necessary for the benefit of the insane person."

Almost all insane asylums furnish printed documents in which the most important sections of the law are shown. Here is one from the Pennsylvania Hospital for the Insane. It is so prepared that if it is read carefully you can see whether or not you are complying with the provisions of the law. I pass one around, that you may see its character.

ORDER FOR THE RECEPTION OF A PATIENT.

I ———— the undersigned, hereby re-

quest you to receive ————, an insane person, as a patient into the Pennsylvania Hospital for the Insane, believing that such detention is necessary for h— benefit. Subjoined is a statement respecting the said ————.

CERTIFICATE OF PHYSICIANS.

We, the undersigned, residents of Pennsylvania, hereby certify that we have, within one week prior to the respective dates hereinafter mentioned, at ————, in the county of ————, separately examined ————, of ————, and do verily believe that the said ————is insane, and that the disease is of a character which, in our opinion, requires that the person shall be placed in a hospital or other establishment where the insane are detained for care and treatment.

We further certify that we have been actually in the practice of medicine for at least five years, and that we are not related by blood or marriage to the said ————, nor in any way connected as a medical attendant or otherwise with the Pennsylvania Hospital for the Insane or other establishment in which it is proposed to place the aforesaid.

CERTIFICATE OF MAGISTRATE OR JUDICIAL OFFICER.

I, ————, a ———— of ———— county, of the State of Pennsylvania, do certify that the foregoing certificate was duly ———— to before me, by the above-named ———— and ———— on this ———— day of ———— 188—, that the signatures thereto are genuine, and that the signers are physicians of good standing and repute.

STATEMENT.

(If any particulars in this statement be not known, the fact to be so stated.)

Questions.

1. Name of patient, with Christian name at length.
2. Sex and age.
3. Residence for the past year, or so much thereof as is known.
4. Occupation, trade, or employment.
5. Parents, if living.
6. Husband or wife.
7. Children.
8. Brothers and sisters, and the residences of each of these persons.
9. If not more than one of these classes is known, the names and residence of such of the next degree of relations as are known.
10. Name and address of all medical attendants of the patient during the last two years.
11. A statement of the time at which the insanity has been supposed to exist, and the circumstances that induce the belief that insanity exists.

You have here four distinct matters:

1. The order for the reception of the patient.
2. The certificate of the physicians.
3. The certificate of magistrate or judicial officer.
4. The statement.

The order or request must be signed by some relative or friend of the patient. The certificates have already been considered.

With reference to the statement, the law says: "There shall also be delivered to the person or persons having supervision or charge of the house, a written statement of the following facts relative to the person to be detained, signed by the person or persons at whose instances the insane person has been removed and detained, or if the facts be not known it shall be so stated." (The name, age, residence, occupation, etc., as indicated in the blank "statement," follow.)

This statement must go with the patient, and I call attention to it for the reason that it is not to be signed by the physician. It must be signed by the person at whose request the order was made for the detention of the insane individual. Most of these answers can be made by any member of the family, but often great difficulty is encountered in getting answers to the questions as to the time when the insanity began, and the circumstances inducing the belief that insanity exists, so that the physician sometimes fills up these blanks in the presence of the relative or friend. He should not, however, sign his name, or anybody else's name. Where the relative or friend is intelligent enough, it is better to allow him to fill up the blank. It is better to have an unbiased, non-professional, non-technical statement of facts. If you do the work, I would suggest the avoidance of certain expressions, such, for instance, as "delusion," "imperative conception," and the like, for these are technical terms in reference to insanity. You should not say that the patient has delusions as regards the marital relations, or hallucinations as regards hearing voices. That is not the way in which the unprofessional friend relates it. What you should say is that the patient

believes that he hears voices, that he believes that belladonna was put in his coffee this morning, that certain persons are pursuing him, etc.

Here is a point. The question whether these are delusions or not must be decided by surrounding circumstances. Facts should be given, not opinions.

These statements are sometimes of great value for statistical purposes, and may be of value if suit should be brought. Sometimes extraordinary statements are made in these blanks, evidently by the physician or from his dictation. These are sometimes made use of in court to cast ridicule upon a doctor who is defending himself against some charge, and sometimes the ridicule is deserved.

It is not wise in statements of this sort to express positive opinions as to causation. In a certificate which I saw some time ago, it had been put down, in so many words, by the physician, that the insanity was due to syphilis. This statement was signed by a member of the family, I believe, by the wife. You can see how unwise a procedure of this kind might be. Supposing that the insanity is dependent upon syphilis, and that it is important, as it is, that this should be known, it would be better for the physician to send a private statement to the hospital than to put it in a document that is to be signed by some member of the family. Such a statement made in this way might bring up questions of law, independent of those connected with the insanity of the patient.

To show how ridiculous some of the statements given to prove insanity are, here is one mentioned in a work on jurisprudence. It was cited as indicative of insanity in an old lady, that she kept a cockatoo! This was one of a very few facts. In another case, it was considered an indication of insanity that the alleged lunatic, when asked, did not know how much money he had in his pocket!

Communications.

STRETCHING OF THE SCIATIC NERVE FOR RHEUMATISM.*

BY J. C. M'MECHAN,

Of Cincinnati, Ohio.

Franz T., a German, was admitted to the hospital July 23, 1883, æt. 39. Had been in America 17 years. He first noticed slight stinging pains in his hip January 1, 1883. This gradually increased. He was able to continue his work as a compositor most of the time till the last of June, when the pain became so intense that he was confined to his bed. Dr. Gustave Zinke was called, who diagnosed the case sciatic neuralgia. He treated him for some time, then sent him to the hospital unimproved. The patient said there was no family history of neuralgia or rheumatism. Had gonorrhœa, but had not had syphilis, and presented no symptoms of this disease. There seemed to be no trouble whatever but the sciatica. He could give no cause whatever for the neuralgia, unless it was constantly standing at his work. He suffered intensely, and most of the time could not leave his bed. The severest pain was between the middle of the thigh and the trochanter, along the course of the sciatic nerve. Hypodermic injections of ¼ increased to ⅔ of a grain of morphia three times per day were given. Large doses of quinia were administered. Chloroform and ether were injected over the nerve. Iron, arsenic, atropia, gelsemium, iodide of potassium, aconite, and various other remedies were tried. Massage and the various liniments were used, also blisters. Under the influence of chloroform, the region along the course of the nerve was burned with an iron heated to a white heat. This was repeated several times, but afforded little relief. The only relief obtained was from morphia hypodermically, but this failed to cure. He remained at the hospital four months, leaving on the last of November. He remained out eight days and returned, remained a short time, went out again, and was readmitted December 31, 1883. Before his last admission, he attended the clinic of Prof. Ransohoff, Medical College of Ohio. The doctor advised stretching of the sciatic nerve for the neuralgia. On the 24th of January, 1884, after his return to the hospital, the operation for nerve-stretching was done. Drs. Krouse, Longhead, McKee, Wilfert, and Fibbe were present and assisted. An incision of three inches in length was made, and the nerve easily brought into view. By means of the finger it was elevated from its proper position, but after manipulating it for a few moments it was grasped by the whole hand and strong traction made downwards. Then the same amount of traction was made upwards. Sufficient force was then made to lift the lower half of the body from the table by means of grasping the nerve and lifting. Traction in each

* Read before the Cincinnati Academy of Medicine.

direction was then kept up for a moment. The nerve was then replaced in its proper position and the wound sewed up and a solution of carbolic acid applied. For a few days after the operation the patient suffered considerable pain, but this grew less after a short time and he became comparatively comfortable. The wound was four weeks in healing. The patient remained in bed until the 1st of April. During this time the most pain experienced was from the knee down to the foot. April 19, 1884, he left the hospital on crutches. He still had slight pain in the nerve, but went to work in a few days. After working one day he laid aside his crutches and walked with a cane. For the following six weeks he still had a little pain, which gradually left. About the middle of July he dispensed with the cane, and felt quite well. A few weeks after the operation, the patient's general health began to improve, and he grew in flesh and strength. During his illness he became thin and anæmic, but in July, 1884, he was as strong and healthy as he had ever been. The patient had no return of the sciatica when last seen, in September, 1884, and he was still able to attend to his work. In the earlier part of 1885 he left the city for New Orleans, still in a good condition. Since then it has been impossible to hear anything from him.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Dr. W. H. Parish.

Fibroids of Uterus and Abscess of Cellular Tissue.

This woman has been before you on a previous occasion. She is thirty-eight years old, has been married six or eight years, but has had no children. She has a large protuberance in the abdomen, which very much resembles a hernia. In 1883 she was admitted to the medical wards of the hospital with a tumor filling the lower half of the abdomen, which, at the time, was diagnosed as an inflammatory tumor, a pelvic peritonitis and cellulitis. After a few months it began rapidly to enlarge, and fever and chills warned us of the formation of pus. Nothing was done, and in a short time there was an escape of a quart of pus from a point near the umbilicus. She was then transferred to the wards for diseases of women. While the opening existed it continued to discharge pus; it would occasionally close, when she would have an elevation of temperature and recurrent chills; she became exhausted, and was bed-ridden. We now diagnosed fibroid tumor of the uterus, with inflammation and abscess in the superjacent tissues. The woman was an ironer by occupation, which brought her abdomen constantly into contact with the edge of a table, and this friction caused inflammation in the cellular tissue about the fibroid. Whether the inflammation was intra- or extra-peritoneal, we could not then determine. I made an incision in the median line and came upon a suppurating track, the entire length of which I cut up. As there was a tumor, I was urged to open the peritoneal cavity and explore. This is a dangerous procedure, because you make a communication between the suppurating track and the peritoneal cavity. However, it was done, and tumors were found adherent to everything—to have removed them would have been almost necessarily fatal. The abdominal viscera were all glued together. So the external wound was brought together, and for a few days union went on nicely. Then there was a chill, and the union that had taken place broke down, the wound gaped, and there were evidences of constitutional sepsis. Under stimulation, an abundance of quinine, and disinfection with carbolic acid, she got well, but, as the healing was by granulation, the resulting scar was broad and liable to stretch. The abscess was found to be in the loose areolar tissue. I have seen the pus in extra-peritoneal abscesses get up almost to the diaphragm. When the pus accumulates rapidly, and extends laterally and posteriorly up towards the kidneys, we may be quite sure that it is extra-peritoneal; but even in these cases it may extend up in the median line, but to do so it must have some other guide than the normal anatomy of the part, which is furnished in this case by the adhesions caused by the tumor. The obliterated hypogastric artery and the urachus offer tracks to determine the direction of the pus. This woman is now very comfortable, using a binder to support the abdomen, and she does not want anything done. In making an examination, we must handle the abdomen gently, else we may excite inflammation. There is also, in this case, a hernia, due to the stretching of the cicatricial tissue. Her menses are regular, though occasionally she has pain. As a surgical procedure, we might remove these tumors, with the consent of the patient, after having fully explained to her

the risk. When the abdomen was open, I looked for the ovaries, but they were so imbedded in the inflammatory mass that I could not isolate them.

Peculiar Case of Puerperal Sepsis.

This woman, aged 19, with a good family history, was recently confined, and did well up to the seventh day. On the evening of that day the temperature rose to 100⅘°, and on the eighth day to 104⅘°, from which point it irregularly descended, until by the thirteenth day it was down to 100°, and it has now been normal for three days. On the fourth day from delivery the left breast became a little hard, and the milk disappeared. An oitment of belladonna and mercury was applied, and the next day a rash like that of measles appeared on the chest, the next day showing itself on the face and back. There was no sore throat, and she was in good spirits. In three days the breast yielded to treatment. The rash was much like that of scarlet fever, but lacked some minor features; it was not in numerous red points, but there was a general redness, more like that of erysipelas, but there was not the swelling of the latter disease. The rash on the arm was not a diffused redness, but was more like that of measles. The tongue during the eruption was not strawberry-like, as in scarlet fever, and there was no coryza as in measles. Desquamation commenced on the fourth or fifth day from the beginning of the eruption, and that over the face was very decided. There was no rise in temperature before the eruption, in fact, none until the commencement of desquamation. This woman had scarlet fever and measles when she was young, but, of course, she could have a second attack. There is a flushing of the surface, due to septic poisoning, that will much resemble scarlet fever. There had been no cases of scarlet fever in this woman's ward, and no cases developed from here, while the disease is so extremely contagious, but we have had one marked case of septicæmia. Playfair and others believe that if a woman who is near confinement is exposed to the virus of scarlet fever, it will remain latent, and after delivery she will have a very violent puerperal fever.

Dr. Parish presented to the class the uterus, ovaries, and Fallopian tubes from the Atlantic City girl (see Reporter, November 7, 1885, page 529). The left ovary (as diagnosed at the time) was found prolapsed and behind the uterus, low down and enlarged, but not adherent, as he previously thought. Both ovaries were cystic, containing a transparent fluid. Small cysts generally cause dysmenorrhœa. The tubes are adherent to the ovary, and the ovarian extremities are occluded. Unlike Dr. Goodell, Dr. Parish thinks there is too much conservatism in this country about the removal of the ovaries. This is a case in point; had this woman's ovaries been removed when she was in a condition to be operated upon, she would have probably recovered; but it was delayed, an exhausting diarrhœa set in, and she died.

Service of Dr. J. William White.

Syphilitic Iritis.

This is a very frequent accompaniment of secondary syphilis, and it is very obstinate and annoying. The first symptom oftentimes is headache in the vertex over the eye, which is very intense, soon followed by lachrymation and intolerance of light. The iris loses its glistening appearance, and becomes dull, and if the iritis has lasted for some time, the circular shape of the pupil is changed by adhesions that bind it down. There is intense redness of the entire anterior portion of the globe of the eye. If adhesions have taken place, they may sometimes be broken up by the use of atropia and mercury pushed to ptyalism, but generally they are persistent, and we are liable to have recurrent attacks of iritis, from which relief can only be obtained by iridectomy. Iritis requires very prompt treatment. If we find the iris dull, and particularly if there is congestion, we must at once place the patient in a dark room and apply leeches to the temples, taking away eight or ten ounces if the patient be vigorous. Follow this with a blister the size of a half a dollar, and leave it on for several hours; apply also a blister to the nape of the neck, and drop into the eye every three or four hours a three or four grain solution of atropia. You should also, as I have said, push mercury to ptyalism, and in conjunction with its internal administration, use blue ointment and cosmoline by inunction. This will be a good treatment even for non-specific iritis.

Lithotomy.

Before performing the operation on a man aged forty-five, who, for thirty years, has had more or less trouble with his water and hæmaturia, and upon whom the crushing operation had been performed last September, Dr. White made some general remarks on the operation. Ordinarily, litholapaxy would be indicated in this case, but as there

is marked inflammation of the bladder from ammoniacal urine, he thinks that the bladder needs drainage which will be secured by the lateral operation, which will also afford a means for local treatment. He would not consider this decision a mistake of judgment if he only found fragments, because it will afford the required drainage. If he were operating solely for drainage, he would do the median operation, but when there is a stone and he is not sure of its size he prefers the lateral operation, because it gives more room. He prefers the supra-pubic operation when the stone is too hard to crush and too large to remove through the perineum. Always satisfy yourself that the stone is in the bladder *immediately* before operating; it will not answer to have found it the day before, because, if small, it may have been passed off, and when you enter the bladder you will be mortified to find no stone. Eminent surgeons have made this mistake. It will be well to try to touch the stone with your fingers when you have opened the bladder, for the sound may go into a false passage and thus deceive you.

PENNSYLVANIA HOSPITAL.

Service of Dr. Morris Longstreth.

Impaction of Fæces.

This colored man has an inflammation of the right iliac fossa, about the beginning of the colon, and we will inquire into its nature and cause. Last summer he was in this hospital, suffering with diarrhœa, for which no definite cause could be assigned. After the diarrhœa, he was troubled with constipation. He was re-admitted to the hospital December 8, complaining of pain in the region indicated, which had existed for two weeks. For some time after the diarrhœa his bowels were fairly regular, then the constipation, which has been mentioned, came on and after going two days without a passage the pain supervened. When he came in, the abdomen was very sensitive to the touch, and I could feel a hard mass. He had had some treatment outside, without avail. His tongue was dry, but not coated; the temperature was about normal, and his abdomen was distended and tympanitic. In the right iliac fossa there was a swelling, which is still more or less apparent. The tympanites has gone, but the pain and tenderness are still here. This mass is evidently an accumulation of fæces in the colon. You will meet a great many such cases, the majority of them in women. Why this is so, I do not know, but it is a fact. These accumulations will often occur, even when the bowels are moving fairly well, and sometimes even when there is diarrhœa. I have seen them associated with profuse diarrhœa. Inflammation has been caused by the accumulation in this case, but this does not always occur. This man has had some local peritonitis. In some cases upon which I have made autopsies, these accumulations have been so great that I could remove many double-handfuls of fæces. The mucous membrane of the gut seems to suffer but little, while the inflammation affects the surrounding tissue. The treatment for general peritonitis is not indicated; this man was given an enema and one-eight grain of belladonna, with one-quarter grain of extract of nux vomica thrice daily. He was restricted to a liquid diet, and mercurial ointment was applied on a rag externally; the abdomen was too sensitive to rub it in. The day after his admission, his bowels were moved, but not very freely. December 10 he was ordered tincture of belladonna, three drops thrice daily, and half an ounce of castor oil at bedtime. As some of the impacted fæces were coming away and the pain was less, we could now use purgatives, but they would be interdicted if the pain was on the increase. The ointment was continued. Yesterday his tongue was coated on the back and dry in the centre, and, as the improvement was decided, I ordered him one-twelfth grain calomel and three grains of soda every three hours, to change the action of the intestines. If the mucous membrane be caused to pour out mucus (by calomel) the mass will be softened down, but if powerful purgatives are used before this softening, it might start the trouble up fresh. This treatment will be continued until the tongue clears up.

The Finger-Nails in Disease.

The subject of the finger-nails in disease is a very interesting one and will prove of service to you in many instances. In all morbid actions that interfere with nutrition, the finger-nails share, and the marks of such irregularities are left for some time on the nails. A mere pustule on the finger will more or less check the growth of the nail, and if this pustule be severe enough to cause a febrile condition, all the nails will be affected. If a man breaks his arm, the swelling of the parts will so interfere with nutrition as to affect the nails, and we can detect whether one has been really sick or deceiving us, for these marks will last as long as nine months, or until the whole nail has grown out. Of

course there are no specific indications of particular diseases, but the indications of some trouble that has affected nutrition will be found. If the patient has had typhoid fever, pneumonia, pleurisy, or acute rheumatism, the evidence will be found in the nail. Again, a man may work in a dye-shop, or some similar place that will stain his nails; if he tells you that he has been sick and unable to work for some time, if the whole of his nails are stained, you will know that he is deceiving you, for if he has been away from work for some time, that portion of his nails which has since grown will have the natural color, while the extremities will be stained. You will often come in contact with persons from whom you can get no history; maybe they have been found unconscious, and you can tell whether they have been sick for some time, or whether the attack is sudden, from the nails. Washing the hands and abrasion from ordinary use, will separate the skin from the base of the nail, while if for some time the hands have not been washed or used this will be unbroken. Here we have one who is convalescent from typhoid fever; during the disease his nails did not grow; now they are growing, and we know that he is convalescent. The change referred to consists in a depression, extending one-third of the way through the nail, commencing at the matrix and advancing as the nail grows, until it is finally discharged from the tip, when it reaches which the end of the nail is liable to be very brittle and break. This phenomenon is on the same principle as with the hair, which, when it commences to grow from its socket, in convalescence, is brittle from innutrition and breaks. In such diseases as rheumatism, where there is a sudden onset, a sudden rise in temperature, which is maintained, this effect is more marked, giving us a very abrupt depression, while in diseases of slower inception, as typhoid fever, it is more gradual, the nail gradually sloping on either side towards the depression. When the nail is growing very slowly during the disease the skin about the matrix adheres to it and is dragged forward, but when convalescence is established, and a more rapid growth commences, the nail shoots forward and tears away from the skin. If, as is sometimes the case, you cannot see this depression you can feel it. Sometimes there is no depression, but a more or less marked white line extends across the nail. If we have two attacks of fever, the one following rapidly on the other, as in relapse from typhoid, there will be two lines, which may be pinkish near the root, but become white as they grow out. During an epidemic of relapsing fever in this house in 1869 and 1870, I had the disease myself and I first noticed these white lines in my own person and showed them to my medical friends, none of whom could offer an explanation. I soon noted the same peculiarity in typhoid, and looking the matter up, I found that some old French physicians had recorded cases of malignant fever in which the nails broke off, and in some cases came off entire. I think we do not have such types of disease to-day, for we certainly do not have the nails falling off. Vogel also speaks of this peculiarity of the nails, but he falls into the error of supposing it an elevation instead of a depression. I have taken off the end of the finger in patients who have died and made sections, when I was enabled to see a marked checking of the growth of the nail cells. These observations are important from a medico-legal point of view, and it is well to remember that the marks will last the longest on the nail of the great toe.

A Group of Local Paralyses.

These local paralyses will often bother you very much. An elderly man, who is accustomed to live well, may call on you fearing that he is threatened with apoplexy or paralysis. When you ask why he has this fear, he will say that for several mornings his arm has been numb, he has had trouble in fastening his collar, and that to-day it has not passed off after breakfast as it had done before, but persists, sometimes affecting the whole side; and he may have pain in the sciatic region, which does look as though the loss of sensation and motion might be due to some central lesion. In such cases you will generally find a history of indigestion, and if you inquire closely you will find that the man, who is usually a heavy sleeper, has slept all night on the affected side. He will often deny this, saying that he sleeps on the other side, but if you put a watch on him, you will find that though he may go to sleep as he says, he will soon turn over on the other side (in his sleep) and so remain all night. This man has been in the house for two months; he had a fractured thigh, and when he got up was obliged to use crutches. After two weeks, his right arm commenced to feel as though it were "asleep," and he could not use it as well as the other. The hand is, so to speak, expressionless, it hangs listlessly; there is some slight swelling, some loss of temperature, and the hand is apt to be clammy. The pressure of the crutch on

the brachial plexus has caused this paralysis, and he is recovering under the use of faradization and massage. This other man was before you on a previous occasion, having sustained serious injuries from a fall of coal. At the time of the accident he was supposed to be dead, and a physician was sent for to make an autopsy, but thinking that he detected some evidences of life, he bled the patient, when he commenced to respire, and after a prolonged period of unconsciousness came to himself. During some convulsions that he had, his right arm moved, as well as any other part of the body, but later the whole of this arm became paralyzed. Dr. Da Costa concluded that the paralysis was due to the bruising at the time of the accident. That it did not come on immediately, we can understand, as it would take some time before the oozing from the bruised vessels would organize and make pressure on the nerve. This man is also recovering under the same treatment as the former. This last man works among horses, and, last Sunday, lost the power of his arm from the elbow down. There is no pain at any point; he was not exposed to cold, nor is there any history of injury, nor over-exertion, nor did he sleep on it. We will give him the same treatment, though we are not yet able to express a positive opinion as to the cause. In the first two cases the prognosis is favorable, gradual absorption and restoration of function will take place; but in the latter case, as the man is older and we have no definite cause, the prognosis is less favorable.

Service of Dr. Thomas G. Morton.

Necrosis of the Os Calcis.

We have here a boy about twelve years old, who has many fistulous tracts extending down to the os calcis. I have not yet felt diseased bone, but from the appearance of the part, I am quite sure that there is extensive necrosis of the bone. Necrosis of this bone is not very common; I have but once resected the entire os calcis. I diagnose involvement of the bone on account of the numerous sinuses; when the bone is not affected, but merely an abscess of the superjacent tissue, there is generally but one sinus; here we have two on the anterior surface, four on the inner, and two directly over the os calcis. I will make a U-shaped incision from the internal malleolus posteriorly around to the external malleolus, and turning down the thick flap of skin from the sole of the foot, have easy access to the bone. I find the bone diseased, but will not be obliged to remove it all. We can do much by *prying* out the dead bone. It is marvellous what good results we get in these cases. The drainage will be good from the position of the wound. By wearing a wedge-shaped pad in the shoe, he can walk without a limp. As a rule this necrosis is not scrofulous or tuberculous, but is caused by an injury. In this case the boy ran a long thorn deeply into his foot, which penetrated the deep fascia, causing inflammation and secondary necrosis. I apply the Esmarch bandage, which makes the operation almost bloodless. It has been fifteen months since the receipt of the injury. With a chisel and mallet I scoop out the pieces and at the same time get rid of the pyogenic membrane. If you can avoid removing the entire bone, it is greatly to be preferred; I have left the shell and its attachments, removing only the cancellous structure, and the cavity will fill up. I divide the tendo achillis because there is a tendency to acquired talipes. I will stuff the cavity with carbolized lint, place a drainage-tube through it and put the limb on a tin splint at a right angle.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. J. M. Da Costa.

Alcoholic Hallucinations.

Here, gentlemen, is a man of 45, a varnisher by trade, who has a history of alcoholism for the past ten or fifteen years. He now comes to us complaining of hearing sounds. What kind? Screams and horrible sounds, making him think that a murder is taking place at the door. At one time he had an hallucination of sight. You hear this remarkable statement. When he was drinking most he had them worst. He is not drinking much now, but he has them in a mild form. His pulse is feeble and compressible, and his skin relaxed. The tongue is coated and flabby; bowels irregular; urine sp. gr. 1030, acid, dark in color, no albumen, no sugar. His heart is normal, though somewhat irritable; the liver is normal, and there is no dropsy. He has no headache nor giddiness. Here the diagnosis is clear; the man is suffering from alcoholic hallucinations. He was accustomed to take from twenty to thirty drinks of whisky in an evening, besides what he drank through the day. It is a marvel that we do not find more structural disease. In order that he may get well, he must, of course stop drinking, and this he is doing. I consider this a

fair case in which to use coca. It is an excellent nerve tonic and a slight nerve stimulant. We will give him fifteen drops of the fluid extract in compound tincture of gentian. I am not perfectly clear whether this will be the correct dose; if it causes headache it will be diminished, but if it produces no tension it may be increased to half a drachm thrice daily. The nervous system must also be quieted, and the best remedy for this purpose is the bromide of sodium, fifteen grains, with ten grains of chloral, every hour in syrup, until he rests; but I would not allow more than four doses in any one night. He should also be well fed. I have derived good results from feeding every two hours and a light meal just before going to bed.

Hysteria.

This girl, 16 years old, comes from the country. Five years ago, she was struck on the side of the head, but she got up and walked home. Some time after this she commenced to refuse to walk and to speak save in a whisper. A year later she would cover her face in the presence of strangers. She sits tailor-fashion, preferring the floor, and will use only one particular chair. She will not walk unless urged along by gentle pushing. Her functions are good, hut her temperature is abnormally high, recording 100° and 101°. There is no lesion of the eye-ground. This is an aggravated case of hysteria that needs decided management. We must strengthen her morale. This is really a disease of the nervous system, and if it continues we may have brought about from long disease atrophy of the nervous centres and organic paralysis. The elevation of temperature is a curious point, which I attribute to the fact that her tissues are burning off too rapidly; she is losing flesh. We will rub the limbs with cod-liver oil, flavored with a little oil of bergamot, with occasional dry friction and massage. Good diet and outdoor exercise are more important than drugs. Of drugs, we will commence with Fowler's solution, three drops in compound tincture of cinchona, and simple elixir, equal parts of each, thrice daily. Later we will order the elixir of the pyrophosphate of iron half a drachm every three or four hours.

Sequel of Sunstroke.

John H. S., aged 43, was sunstruck in 1864. Since then he has had much headache. Last June (15th) after being in the sun for some time, he was delirious for several hours, and he subsequently complained of pain, continuous and dull, in the vertex and occiput, which was worse at night and on lying down. There is congestion of the retinal vessels, but no distinct lesion. His heart acts strongly and rapidly, and there is a systolic murmur at the right base. The temporal vessles are enlarged; the pulse is firm and full, and the cardiac impulse and dullness is extended. There is no ascites nor œdema. These headaches are partly due to the sunstroke and partly to the hypertrophied heart. The treatment must be that for active cerebral congestion. We will act steadily on the bowels, with one or two drachms of Rochelle salts every morning. His diet will consist of milk and vegetables and very little meat. We will give him bromide of ammonium gr. xv, tincture of aconite root gtt i in simple elixir and water of each ʒ ss., twice or thrice daily, if he continues to suffer much from headache. At times, when he is worse, we will apply mustard plasters to the nape of the neck and use mustard foot-baths.

Rheumatoid Arthritis.

This case is somewhat unusual, in as much as the patient is so young. The girl, 12 years old, has deformity of and pains in her hands and wrists, and when I move the joints I get a stiff, grating sensation. The elbow and the shoulder are slightly affected. There has been absorption of the cartilages. She has never had acute rheumatism, but has been always rather delicate. We will give her cod-liver oil (which I prefer to use pure) a dessertspoonful thrice daily, and the syrup of the iodide of iron, twenty drops thrice daily. The joints will be steeped in hot water with soda twice daily, and worked thoroughly; when more limber we will use blisters.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Stated meeting, November 16, 1885. The President, C. T. Parkes, M. D., in the chair.

A Report Embodying Two Hundred Cases of Tonsillitis,

Was the title of a paper read by Dr. J. M. G. Carter, of Waukegan, Illinois.

After detailing the treatments which had been employed in the cases, the author advanced the theory that since the great majority of the cases occurred during March, April, and May, when northeast winds pre-

vailed, carrying landward more moisture from Lake Michigan, these winds must be one of the causal factors in the production of tonsillitis. Also, the test for ozone during these months showed a greater percentage of ozone in the atmosphere. Another fact was noticed, that a great many cases occurred in rheumatic patients. The author was of the opinion that the epidemic of cases detailed was due to the damp northeast winds, containing an excess of ozone, and to unusually disturbed electrical conditions of the atmosphere. The author grouped the two hundred cases, without classifying them, into cases of simple, diphtheritic or scarlatinous tonsillitis. He mentioned, however, the fact that cases of simple tonsillitis were often accompanied or followed by attacks of diphtheria or scarlet fever among other members of the family.

DISCUSSION.

Dr. F. O. Stockton said: "We have tonsillitis in nearly all the eruptive fevers, usually following, and occasionally preceding them. The author refers to cases having diphtheritic patches on the tonsils; I think he has confounded these diphtheritic cases with what we specialists call follicular tonsilitis. It is not a diphtheritic condition at all, but resembles it very greatly, so that in a differential diagnosis these cases are very often confounded. In regard to the temperature going up to 104°, it is my experience, and that of authorities such as Cohen, Bosworth, and Robinson, that it ranges from 102° to 103°, seldom more than 103°, usually 102°. In the treatment of tonsillitis I have never found a gargle effective. In diphtheria or acute tonsillitis you can give chlorate of potash, or any other drug, but where a man has a pain in the angle of his jaw and a throat so sore he cannot swallow, if you can get him to gargle you can do more than I can. Ice held in the mouth until it dissolves is good, also powder or tincture of guaiac and tincture of aconite internally, but never give more than three doses of aconite in one day. Occasionally, if yon see a case is going on to suppuration, use hot applications externally and internally in the way of steam; otherwise never use hot applications. My idea is that heat promotes congestion more than cold, and my experience is that where cases are treated, some with cold and others with hot applications, the cold in connection with other treatment, guaiac and tincture of aconite, is most successful. We ought to settle this question of tonsillitis. What is acute tonsillitis, and is there such a thing as acute tonsillitis? To me it is a misnomer. The abscess seldom forms in the tonsil; it is behind it in the loose connective tissue; and in opening it we cut behind or above the tonsil."

Dr. C. W. Earle said: "I would like to ask Dr. Carter if there was any appearance of contagion in any of the cases."

Dr. J. M. G. Carter said: "Frequently the disease will attack everybody in the family, old and young, and just as frequently but one or two in the family have the disease. It sometimes appears to be contagious."

Dr. G. C. Paoli said: "Tonsillitis is a very common disease in Chicago, especially among children. It is certain that there are different degrees of tonsillitis; there are light cases in which very little medicine is required, and again there are strumous children who are very susceptible to the changes of weather, and in inclement weather get wet and have tonsillitis. In some cases one tonsil is affected, in others both, or the pharynx. There are grave cases that cannot be cured in one week, or two, cases that develop into hypertrophy of the tonsils. In regard to treatment: a light case does not require ice, and a person with malignant scarlatina with tonsils affected would take cold from the application of ice. We should discriminate, and in malignant cases where the tonsils are inflamed should be careful about applying ice. In the use of aconite with children, we should be very careful, as in fever it diminishes the circulation, and I would not recommend its general use unless you can see the patient two or three times a day and watch the effect of the aconite. A simple thing to use is a little potash with tincture of iodine. In scarlatina complicated with diphtheria it is better to use very little medicine. I have nothing against chlorate of potash, however. I read a very interesting paper by a professor in New York, his name I do not now remember, who says that observation has shown that chlorate of potash has often produced nephritis, and I think great care should be taken in its use."

Dr. R. Tilley said: "One of the points brought forward by the author is the use of kerosene. I remember that Besnier, a professor of skin diseases in Paris, says that kerosene is used extensively by the laity, but he regards it as a dangerous remedy in the hands of people generally, and a very inefficient one; he was speaking, it is true, of the treatment of itch. I protest against the use of the terms ozone and electrical conditions of the atmosphere: we know practically nothing about either."

Dr. J. M. G. Carter said that he was obliged to leave in order to catch the train for Waukegan, and expressed regret that he could not remain and reply to the criticisms upon his paper.

Dr. W. E. Quine said: "An interesting feature of the experience embodied in the paper is the obvious failure of the writer to differentiate infectious from non-infectious tonsillitis. I presume it is a matter of familiar observation to all who have been long engaged in the practice of medicine, that many cases of follicular tonsillitis occur which baffle the judgment of the most experienced physician to determine with precision whether they are infectious or non-infectious. I have often seen in my own practice cases of this kind. Often one member of a family, probably the first one attacked, exhibits plainly marked features of simple follicular tonsillitis, and those of the family who sicken afterwards exhibit the phenomena of diphtheria, or less frequently, scarlatina. The text-books do not give a reliable guide to diagnosis, and if any of my colleagues know of means by which cases of this kind can be differentiated with certainty, we would like to know them.

"One gentleman has alluded to the opinion of an eminent professor in New York; I remember that Jacobi, who is, perhaps, the person referred to, in a recent article maintains very vigorously that many cases of so-called tonsillitis are in reality immature cases of diphtheria, and he stoutly maintains that there are many cases of diphtheria never having patches in the throat, and where the patient walks on the street and communicates the disease freely to those with whom he comes in contact."

Dr. Sarah Hackett Stevenson said: "Last February I was called to see a lady who had frequently suffered from tonsillitis. She was 'subject to quinsy.' I suggested that her child should not be kept in the same room with her, as the case seemed more than ordinarily violent, and gave the usual treatment for quinsy; the disease went on to suppuration. I was called out of the city after one of the tonsils had discharged, and during my absence, about five days, her child was attacked with malignant scarlet fever, and died before my return. This is the first case in which I ever suspected that a benign form of tonsillitis might produce a malignant form. Since then, I have watched all cases, however simple they may seem."

Dr. C. T. Fenn said: "I think we should all take an interest in this work, especially in the most practical suggestions of Dr. Earle. The fact is, that to regard these cases all as malignant, is to be on the safe side. A case of simple tonsillitis has a tendency to develop into diphtheria. I protest against the folly of attempting to distinguish between mild and simple cases of tonsillitis and diphtheria. In regard to treatment, I have no use for gargles or washes; I will not force open the mouth of a child and cause it to cry, but steadily and persistently, every fifteen minutes, I will give such medicines as the child will pass over the tonsils when swallowing."

Dr. J. S. Knox said: "I regret that the paper is so general, the author evidently grouping together a variety of cases of tonsillitis of different classes. There is undoubtedly an inflammation of the tonsils due to eruptive diseases, such as small-pox and scarlet fever, and there is a tonsillitis which is purely catarrhal, and another which is purely due to diathesis, and which is rheumatic or syphilitic. The treatment differs accordingly. I think there is an error as to the value of chlorate of potash; better results will be obtained from the use of bicarbonate of potash, the value of the drug lying in the fact that it is a potash salt; and I think that the bicarbonate of soda would be still much more efficient. Where the hyposulphite of soda would do good, the salicylate would do more."

Dr. J. J. M. Angear said: "It seems to me that if we remember that there is such a thing as resistance, the absence of which is susceptibility, it will explain some, if not all of these difficulties. We can readily imagine that a robust, healthy child with strong resistance to morbid influences, and especially that of diphtheria, on exposure, would have simple tonsillitis (abortive diphtheria); but suppose that his brother, with a strong susceptibility, is exposed to the same morbid influences, he will develop a case of undoubted diphtheria.

"In diphtheria, we have an inflammation with fibrinous exudation which breaks down the mucous cells and forms the diphtheritic patch; this furnishes a nidus for the micro-organisms, which go on secreting or fermenting their peculiar virus, the absorption of which contaminates the whole body, and now we have a constitutional disease. Will not this explain a large number, if not all, of those cases where four or five children in a family are taken down apparently with simple tonsillitis, and some one child that has not their resistance is attacked with undoubted diphtheria? In this house we have tonsillitis, and our neighbor severe diphtheria. By remembering these pathological facts, we shall see that it is, or it may be, all the same morbid influence here and yonder—here, recov-

ery in a few days; there, death in a few hours."

Dr. F. O. Stockton said: "In acute tonsillitis I think it will be found that ice is the proper treatment in the first stage, before suppuration has begun. It is very seldom that pus is located in the tonsil; it is behind the tonsil. With regard to a differential diagnosis between diphtheria and tonsillitis, there is almost always in diphtheria a regularly graded rise in the temperature; in acute tonsillitis, so-called, or follicular, the temperature is not regular; it rises at a jump, the attack comes on suddenly, begins with a chill immediately followed by fever; in diphtheria there is a gradual rise, going up one day, dropping the next. I think if we took a record of given cases of diphtheria and tonsillitis, we would find that a regular rise in temperature in diphtheria occurs, as in the essential fevers.

Periscope.

Germain See on Alimentation.

The Paris correspondent of the *Lancet* says that Professor Germain Sée, in opening his course of clinical lectures for the winter session, selected for his subject "Alimentation," or dietetics. He divided the subject into two parts—first, the dietetics of man in health; secondly, the dietetics of man in disease. The latter he would term "alimentary therapeutics." He began by defining an aliment as a substance containing the elements capable of repairing the waste of the tissues of the body, which is going on incessantly, as well as for the removal of the force and heat, which are also incessantly expended in the performance of the various functions of the organism. This led to the consideration of what the professor termed physiological diet, which consists of from 125 to 135 grms. of nitrogenous principles, obtainable from 250 to 300 grms. of muscle or of albuminates, from 84 to 100 grms. of fat, which is the combustible principle of the economy, *plus* 250 grms. of carbo-hydrates furnished by 300 to 400 grms. of farinaceous substances or of sugar, without counting water, which favors the organic changes, as well as the mineral elements, which enter into the composition of all the liquids and tissues of the body; finally, oxygen, which is the burning principle, destined to revivify without cessation the corporal tissues. In anticipation of entering more fully into the composition of what should be the daily ration of a man in health, the professor would say, in general terms, that although green vegetables contain nothing nutritive, yet they have their utility, and must not be discarded, being a necessary element in the daily rations. Gelatine is another substance that has been greatly misrepresented because the *rôle* it plays in the process of nutrition has not been properly understood. Magendie, and other physiologists of his time, after having experimented with it for ten years, came to the conclusion that gelatine was of no utility whatever in the economy—that is to say, as food. Other physiologists have since proved that gelatine, gelatinous bouillons, peptones, etc., contribute to the maintenance of the forces of the organism, in economizing the albuminoid principles, without its being itself transformed into fat. In developing the subject, M. Sée explained that gelatine may be looked upon as a substance that prevents or rather retards the process of denutrition, and on that account applied to it the term of "substance d'épergne," or, as Gubler termed it, "antiderpidateur." It is, therefore, a useful addition to our diet, not only in health, but in disease; particularly in fevers. Where the process of denutrition goes on at a rapid pace, gelatine, in the form of beef-tea or other concentrated broths, would be invaluable. Any deviation from the above principles, whether in quality or in quantity, must more or less affect the normal functions of the different organs and thus produce disease, and M. Sée parenthetically stated that the Germans were large eaters and the English great consumers of meat, which may account for the greater prevalence of gouty affections among them. Professor Sée attaches the greatest importance to diet in a therapeutical as well as a hygienic point of view. In the treatment of disease it is sometimes even more important than pharmaceutical preparations, as, for instance, in typhoid fever, where a proper selection of food is everything, while drugs serve only a secondary purpose.

Gastrostomy and Jejunostomy.

The *Brit. Med. Jour.*, December 5, says that four good papers on these cognate subjects were read and discussed at the last meeting of the Clinical Society, as will be seen by reference to our report of the proceedings published at another page. The features of the disease, for which the operations were performed, varied in each case. In the first three instances, gastrostomy was done to avoid starvation, as there was stricture of the gullet, due in two of the cases to malignant disease, and in the other case (that of a boy aged 4 years) to the swallowing of a caustic alkali. This last patient, though in a condition of almost impending death when operated upon by Mr. John H. Morgan, has since gained weight and strength. Of the two other cases, one related by Mr. Barwell, and the other by Mr. C. T. Dent, the latter showed how futile the old operation of œsophagotomy would have been, as there were two malignant growths in the gullet, the lower of which completely blocked the tube. In fact, the outcome of all recent discussion would seem to narrow surgical interference in advanced cases of this malady to two chief procedures; either that of introducing the elastic funnel-shaped tubes devised by Mr. Durham, which the patient can wear, and through which a way to the stomach can be maintained, or else the alternative of gastrostomy. The evidence which has accumulated in favor of the tube plan is now so considerable, that it seems worthy of being first adopted; since, if the patient can come to tolerate the presence of this instrument, it offers an immediate means of relief. As a last resort, gastrostomy, as at present performed, is doubtless a much less serious procedure than a few years ago it was considered to be.

Mr. Barwell, for instance, at the end of his excellent paper, showed that, before the period of antiseptics, and of the two-stage method, 31 cases afforded but one recovery; whereas, since that epoch, 135 cases had yielded 58 recoveries, that is, 3.22 and 44.5 per cent. respectively. These later good results, it is to be expected, will, in the immediate future, be still further surpassed, just as ovariotomy has risen from a position of being almost constantly, thirty years ago, a fatal operation, to that of being attended now by a very small percentage of mortality. Then, if surgeons should come to interfere at an earlier stage of the disease, the large number of deaths occurring soon after the operation now ascribable, not to peritonitis, but to exhaustion, might be postponed, at any rate, until a period of many months thereafter. Mr. Golding-Bird's important case of jejunostomy brought to light some of the difficulties which surgeons have to encounter in the operations upon the upper part of the small intestine which disease of the stomach and duodenum entails, if any operative procedure is to be attempted. This case, and that detailed later in the discussion by Mr. Pearce Gould, both point to the conclusion that this operation is decidedly to be preferred to that of pylorectomy, though a larger number of cases than has been hitherto detailed must be published before definite results can be drawn. Apparently, there is scarcely any region in the abdomen now left which has not been appropriated for the performance of some special surgical procedure.

The Results of Laryngeal Surgery.

The *Med. Record*, December 19, says:

The operation of excision of the larynx was, we believe, first performed by P. H. Watson in 1866. He was followed by Billroth in 1873, and later by a number of surgeons, including Heine and Gussenbauer, of Prague; Langenbeck, Caselli, of Milan; Schmidt, of Frankfort; Foulis, of Glasgow, and others. In 1884, Hahn (*Arch. f. Klin. Chir.*, xxxi., p. 171,) collected the statistics of 52 operations for total excision. In 24 of these death followed in consequence of the operation. On the other hand, in 12 operations for partial removal, death followed in only 1 case.

The name of Billroth has been particularly associated with operations upon the larynx, and recently Dr. F. Salzer has collected the histories of the cases occurring in his clinic from 1870 to 1884. These include 11 of laryngeal section, 7 of partial extirpation, and 5 of total extirpation. It appears to one reading these records that nothing could be much more discouraging than Billroth's laryngeal surgery; indeed, a less noted operator would hardly dare publish so unpromising a series of cases.

In his laryngofission cases 10 patients were operated upon 11 times. Of these, the wound healed in 8 cases, but in 6 there was subsequently either death or relapse; 3 cases ended fatally within eight days. The result of 8 operations for carcinoma was very unfavorable, since, out of the 8, in only 1 case was there no relapse (two years and nine months after operation).

In 7 cases of partial extirpation death speedily occurred in 3 instances. Of the 6 cases operated upon for carcinoma laryngis, a relapse occurred, and generally very speed-

ily, in all instances but 2. These, however, had, at the time of the report, been operated upon for only two and four months respectively. In 3 cases the functional result was favorable, the patient regaining a certain amount of voice.

The 5 cases of total extirpation of the larynx is an uninterrupted record of death. The patients all had carcinoma, and all died within from one day to seven months after the operation. One patient, to be sure, recovered from the operation, and died later from a relapse; and a second recovered also from the operation, but died in five weeks from purulent pericarditis.

Out of 22 patients operated upon by Billroth, mostly for carcinoma laryngis, 19 are dead, and 2 more are extremely liable to a relapse.

Billroth's cases are much worse than those collected by Foulis. Of 26 cases of total extirpation, 14 died in consequence of the operation. Of the remaining 12, 3 died of relapse.

Still more favorable are the results obtained by Professor Thiersch, of Leipzig, reported by Dr. A. Landerer (*Deutsche-Zeitschr. f. Chir.*, xvi., 1 u. 2, p. 149, 1882). Of 4 cases of total extirpation for carcinoma laryngis, 1 died in consequence of the operation, 1 died of a relapse three months later, and 2 recovered and had no relapse (seventeen to eighteen months).

Three Cases of Thermic Fever.

Before the Rhode Island Medical Society, Dr. O. C. Wiggin read a paper on this subject, saying:

The cause of sunstroke is not necessarily solar heat, but heat always. The predisposing causes may be summed up in all previous conditions which have tended to debility or undue exhaustion. In a large proportion of cases there is abundant warning of an approaching attack. The most uniform premonitory symptoms are lassitude, feeling of fullness and pain in the head, throbbing of the templess, dizziness, discomfort at the præcordia, loss of appetite, nausea, thirst, palpitation, and scanty urine. The prostration, head symptoms, and palpitation, increase in violence up to the time the patient is lost in insensibility.

Treatment varies considerably accordingly as the heart or the nerve centres are more profoundly impressed. Spasmodic contraction of the heart seems to be the immediate cause of speedily fatal cases. In these cases there is absence of high temperature, and consciousness is not impaired until the sudden dissolution; the skin is at first cool and moist, feet and hands cold, countenance pale and anxious, nose cold and studded with beads of sweat. Symptoms of distress are referable to the heart. Indications in these cases are plainly to restore the action of the heart and the capillary circulation. Hot, and not cold, applications are to be applied to the skin. Stimulants in form of ammonia valerianate, strong tea, and morphia in small doses. Chloroform is unquestionably the salvation of some cases, and it would be of many more, could it be brought into timely use, but unfortunately the heart has ceased to beat, has solidified, so to speak, before aid is forthcoming.

In those cases in which symptoms referable to the brain and spinal cord predominate, cold applications to the entire body are demanded, and are the first remedial agents to be thought of. The vaso-motor nerves are paralyzed. The rise of temperature is rapid and extreme. The excretory functions are nearly in abeyance. Temperature must be reduced as speedily as possible.

Alcohol is seldom required in treating sunstroke. Ammonia valerianate is evanescent in effects, but its action is speedy and unequivocal. Tea is the remedy *par excellence* for sustaining the heart's action. Moreover, if there is a legitimate use of tea as a beverage, it is during hot weather. Opium in some form is of service in the painful symptoms of sunstroke. Leeches or the lancet are indicated in cases of extreme congestion of the brain.

The vaso-motor paralysis, which obtains in thermic fever, necessarily leads to a more or less engorged state of the vital organs. The lungs, next to the brain, are the most frequent seat of congestion. It is sometimes startling to notice the shortness of the interval between the stroke and marked dullness and râles.

Passive congestion of meninges is a common occurrence among convalescent patients. Inability to endure heat for a long time after insolation is almost a constant sequela. The victim of sunstroke but rarely recovers the former standard of health.

Onomatomania.

In the *Med. Record*, December 19, 1885, we read that persons who suffer from agonizing mental distress in their desire to recall certain names are said by MM. Charcot and Magnan to have "onomatomania," or verbal mania. An excellent illustration of this

trouble is given: A young man, aged sixteen, neurotic antecedents, was suddenly taken with the following symptoms:

"While walking in the Champs-Elysées he met a gentleman whose acquaintance he had made during a journey to Rome. The young man stopped and conversed with him for some time. After they had separated he tried in vain to recall his name. Not succeeding, he tried to drop the matter, and think of something else. But the inability to recall the stranger's name pressed upon him more and more. He could not rid himself of the effort to remember it; he became depressed in spirits, his face was covered with perspiration, his hands cold, and he reached his rooms in a state of the greatest agony. After this, he frequently became subject to similar attacks of acute mental distress. To obviate it, he carried with him a memorandum book, in which he put the names of all his acquintances, and to which he could, when in need, refer. This procured him some relief for a time, but his malady soon took a wider range, and he became possessed with an irresistible desire to know the names of all persons who passed in carriages, or whom he met in railway trains. The impossibility of learning their names mortified and exasperated him, until, finally, he would go about avoiding the sight of every one, and at last retired to the seclusion of a country house."

Such is a type of an onomatomaniac. The mental and physical distress may be brought on by a failure to recall the names of persons or of things. The crisis of anxiety and pain ceases when the name is found.

MM. Charcot and Magnan state that this peculiar mental symptom occurs only in persons who have a distinct hereditary psychopathic taint. Every one can see that the symptom is only a morbid exaggeration of the very slight mental discomfort which many persons feel when they cannot recall a name which is tolerably familiar.

The disorder belongs undoubtedly among the milder types of the degenerative psychoses, and is closely allied with the disturbances known as agoraphobia, mysophobia, and *folie du doute.*

Wound of Vertebral Artery; Recovery.

Mr. E. Harrison thus writes in the *Lancet*, November 28:

H. S., aged 25, wheelwright, was admitted on July 13, 1885. The patient on the morning of admission was standing ten feet from a machine for shaving down the spokes of wheels. This consisted of a large wheel on the circumference of which were a number of sharp knives; while the wheel was revolving, one of the knives, becoming detached, flew across the room and struck the patient on the left side of the back of the neck, inflicting a deep wound, which bled profusely. He was seen by a medical man, who plugged the wound and sent him to the infirmary.

On admission the man was much collapsed, and had evidently lost a large quantity of blood. The wound extended from below the left mastoid process obliquely downwards and backwards to nearly the middle line, and was bleeding freely. He was put under the influence of ether and the dressings removed, when the cavity immediately filled with arterial blood. The wound was then enlarged and the finger introduced; one of the transverse processes was felt to be fractured, and by placing the tip of the forefinger between the two transverse processes the hemorrhage was controlled. The whole cavity was then firmly and evenly plugged with strips of oiled lint, a graduated compress applied over all, and a grain of opium prescribed every six hours.

On the third day the patient's temperature was 103° F. Some of the lint was removed and the cavity syringed out with carbolic lotion. On the sixth day he had a rigor, and his temperature was 104.6° F. The deepest portion of the plug was now removed, and there was no recurrence of the bleeding. A few fifteen-grain doses of quinine were given, and subsequently iron. The cavity filled up, and on August 11 he was discharged, with only a small sinus remaining, which healed in about a fortnight. When last seen he was well, and able to resume his work.

Cancer in the Breast and its Relation to Riverside Habitations.

Before one of the English medical societies, Dr. Alderson read a paper on cases of cancer of the breast, with remarks as to locality as a cause of the disease. He gave some interesting particulars as to ten cases, the patients having been under his observation in private practice for several years. In seven of the ten, the cancer was in the left breast. He did not think that their proclivity to the left breast was accidental. Five of the patients were single, five married, two had no children, the remaining three six between them. Whatever influence child-bearing might have on the production of uterine cancer, he believed it had none in the production of cancer of the breast; as an obstet-

rician, he spoke as to this with some confidence. There was no history of rheumatism in any. He thought rheumatism and cancer vicarious; cancer-patients had frequent premonitory pains, but did not develop cancer. Five had their breasts removed, one lived seven years after operation, with four years' complete health, and then came recurrence, excited by injury. One derived but doubtful benefit from operation, the cancer quickly reappearing in the cicatrix, and subsequently developing in the right breast; the patient died just two years after operation. The third (case shown), after several years, was perfectly successful; the cicatrix was so pale and smooth, that Dr. Alderson thought that the patient might prove an example of what had been considered "one of the rarest successes of operative surgery, that is, when it is cut out and never returns." The fourth recurred, and death occurred in two years. The fifth was too recent to speak as to results which were, at present, favorable. Dr. Alderson mentioned that all his cancer patients, uterine and mammary, lived very near the river, some at only an altitude of ten to twelve feet above the mean level of the sea. This question of locality, he thought, was something more than a theory. He quoted the opinions of Mr. Haviland, and made some further observations of interest on the subject.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Mr. A. C. Peale, of the Department of the Interior, Washington, has prepared a résumé with reference to the mineral waters of the United States. From this it appears that there are more than eight thousand mineral springs in the United States already known and catalogued; though it is evident that scarcely any of them have any really scientific value either chemical or therapeutic.

——We have received the first number of a new German-American medical journal, *New Yorker Mediz. Presse.* It will appear monthly, and to judge from the contents of the first number, it promises to be of great value to physicians acquainted with the German language. As the editor says: "It is to be the organ of the German physicians in our country." Dr. D. B. St. John Roosa publishes an interesting article on the "Misuse of Politzer's Method in the Treatment of Ear Diseases." Dr. C. Heitzmann has one on the "Removal of Hair by Electrolysis," and Dr. L. Weber's lecture on "Unusual Symptoms and Complications of Intermittent Fever," also appears in the same number, which, besides other original communications, contains a review of all that is new in medicine, and in general keeps the reader well informed of everything that has occurred and is of interest in the wide domains of our science and art.

BOOK NOTICES.

A Reference Hand-book of the Medical Sciences, embracing the entire range of scientific and practical medicine and allied science. By various writers. Illustrated. Edited by Albert H. Buck, M. D. Vol. i., 4to., sheep, pp., 808. New York: Wm. Wood & Co.

We have here the first volume of a work of great extent and corresponding importance. It may be styled a gigantic dictionary of medicine, on a scale hitherto not attempted in our language. It will require eight volumes, approaching nearly a thousand pages each, large quarto form, double columns, and small print, in order to complete it. The illustrations will be numerous, and not merely wood-cuts, but chromo-lithographs, will be added as required to assist the statements of the text. Nearly every article, certainly every article of length, will be written by some specially competent person, whose name will be appended to it, thus conferring upon it an individual value which otherwise it could not possess.

The first volume extends from the word *Aachen* to *Cataract*, and after looking through a number of articles, we must express our satisfaction at the excellent manner in which the editing of the volume has been carried out by Dr. Buck. He has the happy faculty of knowing just how much one would expect to find in this dictionary, and has displayed sound judgment in his arrangement of the space. The names of the writers are, as a rule, well known to those conversant with current medical literature. They are generally but not exclusively American.

The paper, binding, and press-work are thoroughly substantial, and such as befit a work which is intended to be one of daily reference.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

DIABETES.

This disease, without a pathology, as Dr. Pavy admitted a year ago, or at least without a pathology of which we have as yet been able to learn anything definite, was the subject of considerable discussion at the last meeting of the British Medical Association, and from the observations there recorded, it would seem that this is a most peculiar disease, liable to the greatest variety of manifestations and offering the greatest diversity of behavior.

In Dr. Pavy's private experience, the greatest proportion of cases occurred between the ages of forty and sixty, while in his hospital practice, the greatest liability seemed to be from fifteen up to thirty-five or forty. Why this difference should exist in these two classes of patients is not easy to understand. Again, instances are given which tend to show that a peculiar idiosyncrasy towards the disease seems to exist in certain families, which is probably the case with all morbid conditions, due to a certain inherited similarity of constitution, which it is but natural to expect.

Like Bright's disease, diabetes may go on for years without seriously impairing the patient's health, or it may terminate speedily in death; hence must our prognosis be very guarded, and be very full of loop-holes.

We must be very careful not to formulate a diagnosis from merely one examination, for on one occasion Dr. Pavy examined the urine of a man shortly after breakfast and found sugar—he had, at breakfast, indulged freely in marmalade beyond the assimilative power, and at no subsequent time was any sugar found in his urine.

It is worthy of notice that diabetes insipidus and mellitus may exist together, and you can prove their co-existence in the following manner. Take, for example, a patient who is suffering from thirst, and is passing a large quantity of urine containing sugar, but in whose case, as shown by the specific gravity and quantitative examination, the amount of urine is out of the usual proportion to the sugar present. Put him upon the ordinary restricted diet for diabetes, and the sugar may entirely disappear, whilst the quantity of urine keeps up. Dr. Pavy has seen cases in which, with a disappearance of sugar, the quantity of urine has nevertheless kept up to eight, nine, or ten pints in the twenty-four hours, with a specific gravity of from about 1005 to 1007. The diabetes mellitus has been got under by the dietetic management, but the other has remained. Where the two conditions co-exist, the quan-

tity of water passed is out of proportion to the amount of sugar present. In the ordinary form of diabetes, the amount of urine voided stands in relation to the amount of sugar to be eliminated, the sugar, in escaping, carrying off water from the system with it.

Acute febrile glycosuria is a condition that we must have in mind, and we must also remember that Dr. W. R. Thomas recognizes three forms of diabetes, viz: hepatic diabetes, cerebral diabetes, and diabetes accompanying or following other diseases, as Bright's disease, epilepsy, etc.

The patient who suffers from diabetes owing to hepatic causes is generally a stout man, who has always lived well, and perhaps taken too much stimulants in his time. He is at first florid and firm, and becomes in time pale and thin. These patients have generally a tendency to abdominal obesity, have nearly always been successful in life, and occupy a good position.

In such cases attention to diet is of great importance, of more importance than in the other class. Indeed, the inattention to diet in the past, the indulgence, has had much to do with the production of the disease, and Dr. Thomas has found that attention to diet, and other directions given, have practically cured many such cases, and they have lived to a good old age, but indulgence has always been followed by a relapse, severe or slight. Sometimes such patients become disgusted with the diet, and it is necessary to be a little more generous occasionally, or the appetite will fail, and the patient will become steadily worse. Remembering that when Verneuil injected syrup into the stomach of a dog, glycosuria immediately appeared, whereas when the same was done with the rabbit it did not appear, because the rabbit's stomach contained a quantity of vegetable matter, which took up or absorbed the syrup, and allowed it to pass out again, only slowly, slow enough for the liver to be able to act upon it, he has always found it beneficial to allow these patients a reasonable amount of green vegetables to act in this way, that is, to take up saccharine juices.

Exercise in these cases is of prime importance, for, when the muscles of the body are made to act, the glycogenetic functions are more rapidly performed, and the sugar which they receive from the blood becomes more quickly split up into its constituent parts. Exercise also tends to promote a more active circulation through the liver and lungs, and is in this way a most important help to us in our treatment of this terrible disease. Opium is beneficial in these cases, but he gives of it as little as he possibly can; of course, in some cases we are obliged to give it in large doses. It is in this class of cases that he believes alkalies will be found of service, and of these soda and potash are the most useful, especially the soda.

The patient who suffers from diabetes from cerebral or neurotic causes is a thin, spare man, who has been an inveterate worker all his life, and worries about every little thing. He has suffered in the past from dyspeptic symptoms, phosphaturia, and oxaluria, and then diabetes crowns all.

Experiment has proved to us that irritation of the floor of the fourth ventricle will produce glycosuria, and section of certain parts of the cord, and of the vaso-motor nerves of the liver, will have the same effect.

Injury to the floor of the fourth ventricle, or the parts around, will have the same effect, and disease of the same parts has been found in diabetes; so all point most decidedly to the influence of certain portions of the nervous system upon the functions of the liver. The exciting cause will, he believes, be found in these cases to be some great mental trouble—a great loss of money, some family trouble, or the loss of a dear relative.

He has found that, in these cases, mental rest and change are of prime importance in curing. The mischief has been brought on by brain work of some kind, and removal of the cause will often do much towards promoting a cure. He once had a patient under his care who was in business. Although he worked hard for years, he could not make it pay. As he was suffering from diabetes, and was steadily becoming worse every day, he recommended him to give up the business and to seek for a situation as manager. He accepted the advice, and although for a considerable time the sugar still appeared in his urine, he at last became quite well. Removal to another place will often act in a marvellous manner. The change of scenery and surroundings tends to divert attention from whatever has been a source of trouble and anxiety.

It is in these cases that he finds the bromide of potassium useful, given at bedtime. It tends to produce sleep, and acts beneficially upon the cerebral blood-vessels. Tonic remedies, especially arsenic, are very useful in such cases. Opium he gives if obliged to do so, and it certainly does check the excretion of sugar; but he prefers giving as little of this remedy as possible.

It is necessary to diet these patients, but he finds that they soon become disgusted if we are too strict, and it is advisable often to relax the dietetic treatment.

Exercise is beneficial, as it not only acts well by bringing muscles into action, and stimulating organs, but also diverts from the brain, and supplies it with new, more healthy, and less engrossing subjects to work at.

Dr. Latham believes that there is a close pathological relation between diabetes, gout and rheumatism; and altogether we must conclude that we really know very little about the disease, though the above recommendations may prove of value.

FINGER-NAILS IN DISEASE.

We desire to call especial attention to Dr. Longstreth's remarks on this subject on page 41. His observations are novel, and deserving of great attention. Since he notes that there is a difference in the character of the imprint on the nails of those diseases that are acute and of those that are more gradual in their onset, we may possibly, in time, find certain characteristics for each individual disease. We could hardly hope for this nicety of discrimination, but less likely things have come to pass.

The importance of these observations from a medico-legal point of view cannot be overestimated, and we would urge upon our readers to observe these phenomena carefully and critically, and to report their observations.

Notes and Comments.

Uræmic Paralysis in the Aged.

According to the *Med. Record*, December 19, M. Maurice Raymond, in his service at the Ivry Asylum, has observed and studied a peculiar class of paralytic accidents occurring in the aged. These consist of more or less sudden attacks of hemiplegia, which may involve the face and extremities, or only the extremities, and in which the paralysis is sometimes flaccid, sometimes accompanied with contractures. In those cases which end in death, autopsy reveals no lesion in the brain, but the kidneys are uniformly found to be markedly diseased. M. Raymond divides the cases into three groups. In the first the patients are suddenly, without prodromal symptoms, attacked with hemiplegia, they become comatose, and die either immediately or after a lingering illness. Autopsy reveals neither clot nor softening. In a second class of cases the patients are suddenly taken with a hemiplegia more or less complete. If death ensues, the brain shows only evidences of œdema and some ventricular efiusion.

The third class includes patients who have previously had a cerebral hemorrhage and hemiplegia. Upon this supervenes a new attack of hemiplegia, which, however, does not indicate a new hemorrnage, but rather a partial cerebral œdema and anæmia.

M. Raymond believes that these paralytic attacks in the aged are due primarily to renal disease and uræmia. Œdema and "anoxæmia," are produced by the urœmic poisoning, and M. Raymond quotes an experiment upon a dog to show that the production of partial cerebal œdema and anæmia will cause paralysis.

The Hypodermic Injection of Oil.

A correspondent of the *Brit. Med. Jour.* thus writes:

"It appears that some success has been met with in America in injecting various oils for different purposes; and, among other applications of the method, it has been used in cases of gastric ulcer, in order to supply nourishment. In a case of this sort under my care, which has made very little progress for many weeks under ordinary treatment, and where emaciation is becoming alarming, I have tried hypodermic injection of oil; but the operation causes much pain, and is followed by very painful cutaneous inflammation, so that I have been forced to give up the attempt. I need not say that every step was taken to insure success, the oil used being the purest cod-liver oil, and the syringe previously cleaned in hot water. The oil was injected into the subcutaneous areolar tissue. I shall be glad to hear something of the experience of those who have tried this method of feeding, as it seems a matter of great importance. My patient is daily losing ground under careful rectal feeding, and her stomach can tolerate nothing but a few drops of milk at long intervals. If subcutaneous feeding can be carried out, her life, like that of many others, may be saved. Would deep injection involve danger of oil-embolism? Would it be likely to cause less pain?"

Cirrhosis (?) of the Liver in a Young Child.

Dr. E. Frank Marsh, of Oswego Falls, N. Y., writes to the *Medical Record:*

"On November 13, 1885, I was called to

see a male child, aged two years and eight months. I found him suffering from marked ascites, with elevated temperature, respiration 56, and pulse 150. There was considerable jaundice, urine high-colored and scanty, but no œdema of lower lids, or of feet. He took scarcely any nourishment, but drank eagerly. The mother said the child had been failing steadily for several months. Two days later, I introduced a trocar and drew off nearly two quarts of fluid. The opening did not heal for several days, and the serum continued to dribble away. The operation seemed to relieve the child, and after the removal of the effusion I could make out the liver considerably enlarged, and extremely hard. I pronounced it a case of cirrhosis of the liver. The father died of the same disease a little more than a year ago. The child continued failing till the 28th, when he died. There was no post-mortem examination. Upon investigation, I cannot find a case of cirrhosis recorded in so young a child as this, and in this case the abuse of spirituous liquors was certainly not the cause of the disease."

The Larva of the Flea as a Pseudo-Parasite of Man.

In the *Monat. für Prakt. Dermat.*, Bergh relates the following unique case:

B. S., forty, a drunken, dirty, labouring woman, living alone, had suffered from psoriasis for many years. This had lately spread very extensively, and produced thick masses of scales. There was much itching, so that she scratched often till the blood came. Recently she found in the scales so rubbed off, and in the wounds made by scratching, living worms, and brought these to her doctor in a bottle mixed with scales, sand, and dirt. The doctor, on examining the person of the patient, found similar animals both on herself and in the bed, besides many fleas. On changing her residence and clothes, and after having some baths, she was freed from these pests. The "worms" were dipterous larvæ, and when kept for a couple of days in a glass, developed into the pulex which affects man. The larvæ varied in length from 0.25 to 0.4 cm., and were whitish in color. They were made up of a head and thirteen segments, uniform in appearance with exception of the terminal one. Besides antennæ, the head was furnished with a peculiar organ, which Bergh believes is used for perforating the shell in leaving the egg. The segments of the body bore hairs, and the terminal one was thickly covered with these. The eggs of the flea have been found, according to Hebra and Kuchenmeister, under the nails of dirty persons, but the occurrence of the larvæ has not been previously recorded.

Gastric Ulcer.

From our English exchanges we note that an interesting discussion on the diagnosis, treatment, and pathology of gastric ulcer took place at the Medical Society of London recently, introduced by an instructive paper by Dr. Stephen Mackenzie. The most important feature of the paper was the narration of two cases of apparent gastric disease, in which post-mortem examination failed to reveal any certain evidence of disease of the stomach, though the gastric symptoms were even definite enough to excite more than a suspicion of the presence of gastric ulcer. Indeed, one of the cases had been diagnosed by more than one physician as a typical clinical case of the affection. Dr. Sansom and Dr. C. T. Williams advocated strongly the "starvation treatment" of gastric ulcer. Dr. Angel Money suggested that in a few cases of acute peforating ulcer, the ulceration might be regarded as an accident occurring in the course of apepsia nervosa. Dr. Stretch Dowse went much further than this, and appeared to think that perforating ulcers of the stomach were invariably of nervous dystrophic origin.

Sour Milk in Atonic Dyspepsia.

This seems like a novel remedy, yet Dr. W. O'Neill tells us in the *Lancet*, August 29, that he has found sour milk a good remedy in many cases of atonic dyspepsia, or, at all events, it is a good adjuvant in the treatment of slow digestion where flatulence and a sensation of cramp in the stomach are prominent symptoms. The good effects of sour milk were casually discovered by him some months ago, and since then he has prescribed it with satisfactory results in many cases of indigestion. If the curd of the milk should disagree with a patient, it should be strained off, and the whey can then be given, or taken a short time after meals, warm. A gentleman who suffered much from flatulence and other disagreeable symptoms after meals can now keep himself free from them by drinking, half an hour or so after eating, a tumblerful or half a tumblerful of ordinary cold sour milk, which to him is a most agreeable beverage. He believes the efficacy of sour milk in atonic indigestion is owing in a great measure to the lactic acid which it contains, which acid some physiologists say is one of the ingredients of the gastric fluid.

Sequelæ of an Old Ulcer.

To the Harveian Society of London, Dr. W. H. Blenkinsop described the case of a man aged sixty, of healthy descent but subject to rheumatic gout, who had suffered from an old ulceration above the left clavicle, which refused to heal. Under the influence of cold weather, the left apex became the seat of friction and of dullness on percussion, and two weeks later the presence of pus in the pleura was inferred from the bulging of the three upper intercostal spaces and from the general symptoms. A teacupful of pus was removed from the chest, and the sinus was probed and found to take the direction of the chest cavity, passing along the posterior surface of the scalenus anticus. The patient did not improve; caries of the sternum led to falling inwards of the end of the clavicle, and to pressure upon the trachea, and the patient died. The necropsy showed disorganization of the left upper lobe, limited empyema of the upper third of the left pleural cavity, and free communication between the empyema and the wound in the neck.

Congenital Angioma.

To the New York Surgical Society (*N. Y. Med. Jour.*, November 14), Dr. Charles McBurney presented a man who had a congenital angioma of unusual size upon the right side. The tumor was five inches in breadth and four in depth, and extended from the median line in front to within three inches of the median line behind. The patient stated that during early youth and until within the last seven or eight years, the tumor had bled regularly, and that he had lost large quantities of blood, sometimes as much as a quart at a time. During the last seven or eight years he had been very comfortable, with firm compression of the growth, and had had no hemorrhages. Dr. McBurney felt inclined to advise him to continue with this treatment, and not to have any operation whatever performed. The tumor was not pulsating at any part, was venous, and was of the cutaneous and subcutaneous variety, chiefly the latter.

Syphilitic Ulceration of the Vocal Cords.

To the Society of Physicians of Vienna, Professor Schditzler showed a young girl in whom the vocal cords had grown together. The mucous membrane of the larynx was red and swollen, especially over the arytenoid cartilages, the mobility of which was impaired, On inspiration, the cords separated a little, but two-thirds of the rima glottidis were closed by a membrane, so that only a very small aperture remained for inspiration. The membrane was of a grayish-white color, transparent, and 1½ mm. thick. This condition was due to a chronic ulcerative process of the vocal cords, which, as in most such cases, arose from syphilis. Prof. Schnitzler remarked that he would remove this condition by operation. He had been treating the patient for three years, and he gave an account of the different stages of the process.

The Disinfection of the Hands.

The *Med. News*, December 19, tells us that Forster, of Amsterdam, has make an experimental investigation of the comparative values of different methods of rendering sterile the bacterial dust which is always present on the hands. All the known disinfectants were used, and the so purified finger was dipped in sterilized neutral beef-juice peptone solution.

With one exception, the development in the culture media of fungi, in from twenty-four to sixty hours, was not prevented by the treatment of the finger. Even washing with two and a half per cent. carbolic acid solution was inefficacious. Corrosive sublimate solutions alone, of a strength of from half to one part in one thousand, were found to be of use; and the finger thus treated, when dipped in the most sensitive culture media, induced therein no fungous growth.

The Treatment of Cases of Imperfect and Painful Swallowing.

It has been frequently recommended that we resort to a tube passed through the nose, but we venture to say that comparatively few resort to this procedure, especially in children's practice, because it seems like a very unpleasant method. However, we note that Dr. J. F. Bullar (*Practitioner*, October) states that this is an erroneous impression. As a matter of fact, there was commonly little, if any struggling or apparent discomfort; the children often hardly woke while the tube was passed, and fell asleep immediately after it was withdrawn; and in cases in which the children resisted the passage of the tube it was invariably found that they had more rest and were less exhausted than when constantly troubled with a spoon.

Stricture of the Ileum.

To the Pathological Society of London,

Dr. Gulliver described this case, in which the gut was thickened in all its coats at the stricture one inch above the ileo-cæcal valve; just above it there was a dilatation; below, the ileum was quite normal, as also was the large intestine. The stricture was due to a band of adhesion stretching across the ileum at that point. The patient, a boy aged 10 years, had suffered much from pain in abdomen for six weeks, and to a certain extent for a year. There was emaciation and pain and towards the end vomiting; there was never any intestinal obstruction. After death there was found hemorrhage into the supra-renal capsule, and also a caseous mass in it. In the dilated portion of intestine a large amount of débris was found. He died from chronic enteritis.

Extraction of Foreign Body from Bronchus.

On November 26th, Sir W. MacCormac operated at St. Thomas' Hospital, London, on a young woman, aged twenty-four, who had dropped accidentally into her air-passages, during the extraction of teeth, one blade of a pair of bicuspid tooth-forceps, seven weeks previously. The trachea was opened for fully two inches, and the isthmus of the thyroid divided in order to give more room. Long forceps were passed into the bronchus, and the foreign body, which was fully an inch in length, was found to be fixed about two inches from the bifurcation of the trachea. Considerable difficulty was experienced in removing it, on account of its smoothness and wedge-shape, also from its firm impaction. The operation was prolonged, but the patient bore it well.

A New Dressing for Wounds.

The Paris correspondent of the *Brit. Med. Jour.* (Dec. 12), says that a new article for dressing wounds, called Berthault's taffetas, has just been brought out, which is considered to be superior to the adhesive plasters hitherto used. It is as transparent as glass, and as thin as the skin of an onion; the condition of the surface covered by it is as easily seen as though it were uncovered. This plaster is as elastic as India-rubber: it cannot be traversed by fluids, and is unaffected by change of temperature. Chemically it is inert; neither changed by acids, alkalies, nor the secretions of the human organism.

Bowdichia Major.

At a meeting of the Therapeutical Society of Paris M. Petit read a communication concerning a new alkaloid which he had abstracted from the bark of a shrub used in Brazil in the treatment of fevers and of rheumatic and gouty pains. This bark comes in hard, thick fragments of an ochre-yellow color, has a bitter taste, and resembles somewhat yellow cinchona bark. It is taken from a leguminous plant called Bowdichia major, and known by the natives under the name of sebipira guacu, or sucupira. The alkaloid is said to possess narcotic and mydriatic properties.

Resection of the Ribs for Tumor of the Chest-Wall.

The *Practitioner* for October, quoting from a German journal, says that a case was related by Dr. Maas of an ossifying enchondroma of the ribs, during the removal of which portions of the ninth, tenth, and eleventh ribs to the extent of nearly three inches were cut away, together with the subjacent pleura. The pericardium and retracted lung lay free underneath. The edges of the skin were drawn together with strong sutures, and the healing was so rapid that by the fifth day vesicular breathing was audible at the level of the seventh rib. Healing was complete by the eighth day.

Transplantation of Large Pieces of Skin in Recent Wounds.

The *Practitioner*, quoting from a German journal, tells us that Esmarch brought forward at the German Congress of Surgeons some pictures to illustrate the importance of such treatment. One was a case of lupus of the nose, another a facial mole. The success in both cases was complete; the flaps united by first intention, and the scar was quite insignificant. The conditions necessary for success are — that all the subcutaneous tissue should be cut away, and the flaps laid flat on the raw surface, where they should be firmly secured by a few stitches and a bandage.

Nerve Stretching in the Treatment of Sciatica.

Dr. R. Whitman thus writes to the *Med. News*, December 19:

"In the *Medical News* for January 10, 1883, page 10, I reported a successful case of nerve stretching for the relief of sciatica, performed at the Boston City Hospital by Dr. Fifield. The man has since remained entirely well, though the condition of his life has been most favorable for a recurrence, as he is now a common drunkard and tramp.

As more than three years have now elapsed since the operation, the cure may, I think, be considered permanent."

Cutaneous Anodyne.

Dr. R. G. Gough, in the *Virginia Medical Monthly*, recommends the following prescription as one of the best he has ever found as a lotion for itching cutaneous surfaces, whether the skin is broken or not. He has used it with invariable success, and it has now become a popular application with the local physicians:

℞. Sodæ biborat., ℥j.
Acid. carbol., gtt. xv.
Glycerin, ℥j. M.

Sig.—Apply as lotion with camel's hair brush, or by dropping from bottle on the itching surfaces.

Correspondence.

The Epidemic in Martinsburg, W. Va.

Eds. Med. and Surg. Reporter:

Permit me to say that the papers publishing this locality as being belabored by an epidemic of cerebro-spinal meningitis are gravely in error, as no such disease has prevailed here in epidemic form since February and March, 1875. Last February we had a slight epidemic of acute meningitis numbering about ten cases, all excepting one proving fatal in four to ten days, whilst a number of others, very mild in form, recovered. Cause, extreme vicissitude of temperature and exposure. We have had, however, an epidemic disease prevailing here, which began about the first week in October, and which is now about over with, as no new cases are reported, though many are yet under treatment. The disease is a hybrid between malarial and typhoid fever; or, to put it in better terms, it is a malarial fever of the remittent type, with marked typhoid tendencies. Of this disease there have been not less than two hundred cases, and probably as many as fifty more. The mortality was nil, save two cases in which typhoid fever became pronounced, one of which developed the cerebral symptoms that probably gave rise to the rumor alluded to. The disease presented the following characteristics: A period of malaise of four to ten days, then indistinct chills or rigors, followed by fever, with gradual rise in temperature, always highest in the evening, frequently normal in the morning, ranging from 100° to 103°. Many cases were tertian in character, the temperature being higher every other day. Pulse weak and feeble; marked debility; tongue usually moist, but coated with long yellowish fur; anorexia; not much thirst; frequently severe frontal headache, which usually subsided early in the disease; nausea and vomiting of bile; epistaxis in numerous cases, and abdominal tenderness, most frequently referred to the right iliac region, and occurring only in the graver forms of the disease, more distinctly typhoid, and in which there was hemorrhage from the bowels. There was no disposition to diarrhœa in any of the cases; the dejections for the most part were yellowish and semi-consistent. The average duration of the disease was about 25 to 28 days. The basis of the treatment was quinia, exhibited in various forms, and such other remedies as were required to meet special indications.

The cause of the epidemic is conceded by the local Board of Health to be due to a bad sanitary condition of the city, resulting mainly from contamination of a creek which courses through the corporation, into which the refuse of a distillery finds its way. The frequent fall rains, no doubt, in conjunction with the above-mentioned causes, had much to do with precipitating this epidemic.

S. N. Myers, M. D.

A Monstrosity.

Eds. Med. and Surgical Reporter:

On November 27th at 11 a. m., I was called in consultation with Dr. Bacon of Harveyville, Pa., to see Mrs. B., in her first confinement. She had been in labor since 3 a. m.

Her pains were few and far between. On examination I found what appeared to be the distended membranes, but was informed that the waters had drained away some hours before. The examination appeared to increase the pains, and what I first thought was the membranes protruding. I now found by ocular examination to be covered with a few scattering hairs. The diagnosis was now clear, viz: Hydrocephalic head. Dr. B. made slight traction, and the head was soon born. I administered ext. ergot fl. ℥ss., and the labor was soon brought to an end.

After a period of about twenty minutes, the placenta was delivered by Credé's method. The uterus contracted very nicely, and the binder was applied. The placenta and cord were full of what appeared to be calcareous deposits. Now for the child:

the body and extremities were fully developed; it was a hard matter to tell which sex predominated as it had (with the exception of scrotum and testicles) the sexual organs of both. The head was nothing more than a bag of water. There was no frontal bone above the supra-orbital arch, no temporal bone above the zygoma, and no occipital bone could be felt.

All there was of respiration was one short cough, which took place at intervals of thirty seconds. There was no breathing, no chest motion at all; in this manner it lived for nine hours. Now what appears strange to me in this case is the manner in which the respiration was carried on, and the length of time the child survived. Has any one had a similar case?

E. F. Bonham, M. D.

Fairmount Springs, Pa., Dec. 7.

Self-righting.

Eds. Med. and Surg. Reporter:

At present the New York hospitals are complaining and feeling financial pressure from diversion of a portion of the excise fund, which portion was, until recently, divided and apportioned among them. Our hospitals and dispensaries have grown to be so flourishing from *continual* donations, public and private, that every little while a new one springs up, and, like its predecessors, clamors for public and private aid. This abuse has at present reached to a great pitch. A private doctor and citizen may own real estate and be taxed indirectly to aid medical institutions, gotten up solely for the benefit of the staff, of which he is not a member. All the private doctors are at present suffering from the depredations of these immense leeches—hospitals and dispensaries, general and private. All suggested remedies are utterly powerless. The action of the New York municipal authorities in withholding the money subsidy of the excise fund, is timely, and is the best thing that could have been done. If more than half of the hospitals and dispensaries shut down for want of funds, nobody would be the loser except the people who got them up; and withholding the funds is a step in the right direction.

C. E. Nelson, M. D.

New York City.

—Medical Examiner: "What did your father die of?"

Applicant: "Oh, just *plain* death."

News and Miscellany.

Provisional Regulations

For preventing slaughter-houses, stock-yards, hog-pens, bone-boiling and fat-rendering, and other similar establishments, from being or becoming prejudicial to the public health.

With pleasure we publish the following valuable communication from the State Board of Health:

NUISANCES DEFINED.

1. Whatever is dangerous to human life or health, and whatever renders soil, air, water, or food impure or unwholesome, are declared to be nuisances and to be illegal; and every person having aided in creating or contributing to the same, or who may support, continue, or retain any of them, shall be deemed guilty of a violation of these regulations, and shall also be liable for the expense of the abatement or remedy required.

HOUSE-REFUSE, GARBAGE, ETC.

2. No house-refuse, offal, garbage, dead animals, decaying vegetable matter, or organic waste substance of any kind, shall be thrown upon any street, road, ditch, gutter, or public place, and no putrid or decaying animal or vegetable matter shall be kept in any house, cellar, or adjoining out-buildings, for more than twenty-four hours. Violation of any of the provisions of this regulation shall be punished by a fine of not less than twenty dollars.

NOXIOUS TRADES.

3. No person or company shall erect or maintain any manufactory or place of business dangerous to life or detrimental to health, or where unwholesome, offensive, or deleterious odors, gas, smoke, deposit, or exhalations are generated, without the permit of the Board of Health of the nearest city or borough, and all such establishments shall be kept clean and wholesome so as not to be offensive or prejudicial to public health, nor shall any offensive or deleterious waste-substance, refuse, or injurious matter, be allowed to accumulate upon the premises or be thrown or allowed to run into any public waters, stream, water-course, street, road, or public place. And every person or company conducting such manufacture or business shall use the best approved and all reasonable means to prevent the escape of smoke, gases, and odors, and to protect the health and safety of all operatives employed therein. Any violation of any of the provisions of this ordinance shall be punishable by a

fine of not less than ten dollars nor more than one hundred dollars for each offense.

4. The business of bone or horse-boiling shall not be allowed, unless conducted under cover, the building to be provided with smoke-consumers, and a due regard to be had for cleanliness in the disposition of the offal. No bone-boiling establishment or depository of dead animals shall be kept or erected in any part of this Commonwealth, which is not under the jurisdiction of a local board of health, without a permit from the board of health of the nearest city or borough.

5. No permit shall be granted to any person or persons to carry on the business of boiling bones and dead animals until after a careful inspection of the locality, buildings, and apparatus, and of the plans for conducting the business, by an accredited Inspector of the State Board of Health.

6. No bone-boiling establishments or depositories of dead animals shall be kept or erected in or near to a thickly inhabited neighborhood.

7. The floor of all bone-boiling establishments and depositories of dead animals shall be paved with asphalt or with brick or stone, well laid in cement, or with some other impervious material, and shall be well drained. All such establishments shall have such an adequate water supply as will enable thorough cleanliness to be maintained.

8. The boiling of bones and dead animals, etc., shall be conducted in steam-tight kettles, boilers or caldrons, from which the foul vapors shall first be conducted through scrubbers or condensers, and then into the back part of the ash-pit of the furnace fire, to be consumed, or by other apparatus equally efficient in preventing or counteracting the offensive effluvia.

9. When bones are being dried after boiling, they shall be placed in a close chamber, through which shall be passed, by means of pipes, large volumes of fresh air, the outlet pipe terminating in the fire-pit.

10. All proprietors of bone-boiling establishments not having, on the first day of July, 1886, permits to carry on the business, and violating these regulations, shall be fined fifty dollars for every such offense, and for each month's continuance of the same after notice, and also be liable to an indictment at common law for creating and maintaining a nuisance.

11. The permit Clerk of each local Board of Health shall have provided a book in which to enter the names of all persons engaged in the business of boiling bones and having depositories of dead animals, also, the location of works and appliances as reported by the Inspector, whether licensed or not, the number and date of permits, and remarks.

12. No person or persons, without the consent of the Board of Health of the nearest city or borough, shall build or use any slaughter house within the limits of this Commonwealth; and the keeping and slaughtering of all cattle, sheep and swine, and the preparation and keeping of all meat, fish, birds or other animal food, shall be in the manner best adapted to secure and continue their wholesomeness as food; and every butcher or other person owning, leasing or occupying any place, room or building wherein any cattle, sheep or swine have been, or are killed or dressed, and every person being the owner, lessee or occupant of any room or stable wherein any animals are kept, or of any market, public or private, shall cause place, room or building, stable or market, to be thoroughly cleansed and purified, and all offal, blood, fat, garbage, refuse and unwholesome and offensive matter to be removed therefrom at least once in every twenty-four hours after the use thereof for any of the purposes herein referred to, and shall also at all times keep all woodwork, save floors and counters, in any building, place or premises aforesaid, thoroughly painted or whitewashed; and the floors of such building, place or premises shall be so constructed as to prevent blood or foul liquids or washings from settling in the earth beneath. Any violation of any of the provisions of this regulation shall be punishable by a fine of twenty dollars for each day's continuance or repetition of the offence.

13. No blood-pit, dung-pit, offal-pit, or privy-well, shall remain or be constructed within any slaughter-house. Any one offending against this rule shall be guilty of creating and maintaining a nuisance prejudicial to public health, and shall be required to remove the nuisance within ten days from the date of notice.

14. The owners, agents, or occupiers of all slaughter-houses are required, during the months of June, July, August, and September, to distribute twice in each week not less than twenty-five pounds of chloride of lime about their premises, and also to remove the contents of any manure-pit or manure-pile on the premises, once in each week, the said premises and contents of manure-pits being hereby declared to be nuisances prejudicial to public health, unless subjected to frequent disinfection and cleaning as herein indicated.

15. *All constables and supervisors are en-*

joined, and all citizens are respectfully desired, to give information to the State Board of Health of any violation of the health laws, or of the regulations of the Board, so that sanitary measures adopted by the latter to ensure the health of the State may be fully carried out, and all offenders promptly punished. BENJAMIN LEE, M. D.,
Secretary and Executive Officer,
313 South 15th St., Philadelphia.
November 1, 1885.

Physicians of the Pennsylvania Hospital at a Banquet—a Notable Gathering.

Dr. Henry H. Smith, white of hair and sage of mien, sat in a big oaken chair at the head of a long table in the library of the Pennsylvania Hospital, on the evening of December 10. He is the eldest but one of all the men who have served the hospital as a medical officer. The occasion was the first annual dinner of the Association of Resident Physicians of the hospital who have served the institution in the capacity of medical officer. Reports showed that the Association is flourishing. Dr. Smith is the perpetual chairman. Dr. Reynell Coates, however, now of Camden, who was a resident in 1818, is the eldest member of the Association. He would have presided had he been at the dinner.

The managers of the institution, Messrs. Shinn, Lewis, Jones, Garrett, Shoemaker, and Morris, and Steward William G. Maylin, who has been connected with the institution sixty-three years, were guests of the association. The physicians at table were: Doctors Morton, Morton, jr., Hunt, Hopkins, Fox, J. S. Lee, J. C. Wilson, W. Chrystie, DaCosta, Woodbury, Andrews, Packard, Roberts, Longstreth, Herbert, Levis, H. H. Smith, John B. Shober, Hartshorn, C. H. Chapman, F. Wistar, C. C. Lee, Wetherill, Bradford, J. Ashhurst, J. H. Reeves, Charles M. Wilson, R. Given, W. Pepper, A. Fleming, M. T. Kirkbride, Fisher, Meigs, Darrah, Rhoads, Dullus, McCall, J. J. Kirkbride, Wells, Coaks, W. H. Bartel, Elmer C. Wistar, Gillespie, E. Richardson, J. Chapin, Penrose, Collins, Saerg, W. T. Norris, F. W. Lewis, Joseph S. Neff, C. Wirgman, Orville Horwitz, R. Penrose, Jainez, C. H. Moelair Trotter, Stocker, Van Harlingen, Baum, Tyson, J. G. Richardson, Hutchinson, Brush, Franklin, Harlin, Reed, Taylor, Bray, Bashe, and Ritz.

After the ices had been brought on, Dr. Thomas G. Morton delivered the annual oration, taking for his theme the history of the institution.

Dr. Smith read a paper on the "Pennsylvania Hospital as a Training School for Physicians," and Dr. James J. Levick spoke of the "Physicians of Philadelphia and vicinity prior to 1700." Then Dr. William Hunt sent every one away in a merry mood by some bright and clever remarks on medicine and medical men in general.

Retirement of Sir Joseph Hooker and Professor Huxley.

From the *Lancet* we learn that recently both of these distinguished men retired from the prominent positions they occupied—Sir Joseph Hooker from the directorship of the Royal Gardens, Kew, and Professor Huxley from the presidency of the Royal Society. Sir Joseph Hooker resigns office merely that he may obtain the leisure requisite to prosecute the study of the vast accumulation of Indian plants which still require arrangement and classification, and which are in great measure the results of his own travels and collection. The reasons that have induced Professor Huxley to quit the high office he has held for so short a period are somewhat different. In the first place, with the conscientiousness that arises from a mind ever open to the claims of others, he has often maintained that at sixty years of age a man has completed the active period of his life as a scientific worker, that with hardened and stereotyped ideas he has done all the good work he is likely to accomplish, and that he must leave the path open for other and more active spirits. But, apart from these considerations, Professor Huxley may well claim the leisure which is the reward of toil, and may enjoy some rest from the protracted and intense mental exertion he has made during the past twenty or thirty years. He experienced much dyspepsia, leading to impaired nutrition, anæmia, and general debility, without, however, any signs of organic disease. Following good advice, he went to Italy, and on his return last spring, he found that his residence abroad had effected a marked improvement in his health. The work of the president of the Royal Society is by no means light, and on his return his labors in that capacity retarded his complete recovery. He therefore wisely, though to the regret of the scientific world, determined to resign, and has already felt the benefit of his resolution by rapid improvement in his general vigor and health. There still remains much for so active a thinker to do, both by counsel and in the direction of scientific research,

and we sincerely hope that he will long be spared to stimulate others to advance in the paths which he is about to leave. It is gratifying to learn that a pension of $1500 per annum has been conferred on Professor Huxley, in recognition of his eminent scientific services.

Wyeth's Vaccine Farm.

Down near Westtown, in Chester county, the enterprising firm of John Wyeth & Bro. have started a model farm. It was recently inspected by a delegation of physicians, including several members of the State Board of Health, who found everything to praise and nothing to censure.

It is truly a model farm, designed after a personal inspection of the famous vaccine farms of Europe, and combining in itself the good points of all of them. The operating room and the stables are finished in hard wood, have asphalt floors, abundance of ventilation, and are flooded with light, so that they not only present a handsome appearance to the eye, but possess every sanitary requirement.

The inoculation of the heifers is done by Dr. Zuill, one of the faculty of the Veterinary Department of the University of Pennsylvania, thus insuring the fact that the virus is taken only from those heifers that actually have cow-pox.

The animal (from seven to eighteen months of age) is fastened (on his back), his belly shaved, and inoculated in thirty or forty places. After nine or ten days, if he has had an elevation of temperature, increase of pulse, and the formation of secondary umbilicated pustules (that is to say, elsewhere than where he has been inoculated), the scab is removed from the inoculation and ivory points coated with the lymph, as it flows *spontaneously*, care being exercised not to take the flow that can be excited by rubbing the sore with a coarse rag, for this would give us serum and not true lymph.

From each heifer as many, sometimes, as two thousand points can be coated, and as the farm has ample accommodation for seventy animals, we can readily see that this firm possesses facilities for supplying a very great demand. It is also to be noted that the points are guaranteed for three weeks.

Small-pox in Montreal.

The Montreal correspondent of the *Med. News* says that "the deaths from small-pox during the month of November reached the large number of 874. Still this is only a little more than half the number (1630) of deaths which occurred during the month of October. Up to the end of November, the total number of deaths from small-pox was 3513. The hospitals are still full, and new wings are being opened. The old Hospital of St. Roch's is still occupied, notwithstanding the protests made by the Visiting Governors of the College of Physicians and Surgeons of Quebec Province. Among other things, they said: 'Dirt, foul smells, and mismanagement, are the characteristics of St. Roch's Hospital.' Many patients who have been treated in St. Roch's have given most horrible details of the condition of the hospital and the methods of treatment. It is a perfect black hole of Calcutta, according to many. The doctor was incompetent, the nurses inefficient and neglectful, and the food (so-called) disgusting. Many dying patients could not get a drink of water. Still the Health Board deny everything, and endeavor to make the public believe that it is a perfect sanitarium, and no fault can be found with it, or the incompetent staff that run it. However, the profession are perfectly convinced that the place ought to be shut up, or rather burned down, and all the cases sent to the new hospital, where the air is good, the attendance fair, and there is plenty of room. I fear that we shall have small-pox with us for some time yet, as no efforts are being made to vaccinate the twenty French Canadian babes that are daily arriving and growing up unvaccinated. Fuel is thus continually being added to the flame. Until registration and vaccination are compulsory, small-pox, like the poor, will be always with us."

Dr. Bond and Benjamin Franklin.

Dr. Bond died in 1784 and Franklin in 1790. Yet in all probability Franklin foresaw much to come—the independence of the country, its wonderful growth, the progress of Philadelphia, and the need that the great city would have of a hospital for the care of its injured sick and demented poor. Even the influence that advancing civilization would have in increasing the ratio of insanity must have been apparent to Franklin, since it was for the treatment of lunacy more especially that the Pennsylvania Hospital was designed, and that he had advanced ideas as to administering to minds and bodies diseased may be inferred from the clause he introduced chartering the hospital "for the entertainment and cure of the sick and distempered poor." Extensive as was the hospital he designed, it

has grown greater still, advancing in spite of all difficulties, and now has three large and noble buildings to receive its sick, owns a square of ground in the old city, and has 113 acres in the new city beyond the Schuylkill, containing the finest and best equipped private asylum for the insane in the United Stales.

State Board of Health.

REGULATION IN REGARD TO THE SANITARY SUPERVISION OF TRAVEL AND TRAFFIC.

Upon satisiactory information of the approach to, or the transit through, the Commonwealth of Pennsylvania, of infected persons or goods, it shall be the duty of the Secretary, as executive officer of the Board, to cause the same to be stopped at the State line, or, if found within the limits of the State, to cause such person or goods to be removed from cars, stages, vessels, boats, or other conveyances and securely isolated and disinfected; and he may, if in his judgment the emergency is such as to demand it, call a meeting of the "Committee on Travel and Traffic," to which his action shall be submitted, with his reasons therefor, in writing. But, in cases coming under the jurisdiction of national or municipal quarantine authorities, he shall co-operate with said authorities in all such action.

By order of the Board.

Signed,

BENJ'N LEE. *Secretary.*

Executive Office, 313 *S. Fifteenth street, Philadelphia.*

The Management of Stray Dogs.

The *N. Y. Med. Jour.* notes that the *Lancet* commends a London institution known as the Temporary Home for Lost and Starving Dogs. Owing to the present prevalence of hydrophobia in London, there has lately been a great increase in the number of stray dogs cared for by the institution, for they are brought to its doors by the police. As many as nine hundred were received in the course of six days. Our contemporary points out a conspicuous service to humanity rendered by the home, in addition to the benefit to the dogs—that, namely, of keeping sick animals under watch until it can be determined positively whether they are or are not affected with rabies. If London, in the face of almost an epidemic of hydrophobia, can afford to be so humane to vagrant dogs, what excuse is there for our annual period of legalized brigandage, when the chief occupation of a set of miscreants termed dog-catchers is to steal or forcibly capture animals that are in no sense vagrant, merely that they may exact ransoms?

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED DECEMBER 26, 1885.

Purviance, George, surgeon. To proceed to Chicago, Illinois, as inspector, December 23, 1885.

Guitéras, John, passed assistant surgeon. To proceed to St. Louis, Missouri, for duty, December 23, 1885. Granted leave of absence for seven days. December 26, 1885.

Urquhart, F. M., passed assistant surgeon. To proceed to Charleston, South Carolina, for temporary duty, December 23, 1885.

Bratton, W. D., assistant surgeon. Granted leave of absence for twenty-two days, December 22, 1885.

McIntosh, W. P., asst. surgeon. Granted leave of absence for fourteen days, December 22, 1885.

The Illinois State Board of Health and the Regulation of Medical Practice.

A decision is reported to have been made recently by one of the Illinois courts, which, it is thought, will have the effect of greatly abridging the Board's power in the administration of the Medical Practice Act. It seems that a graduate of the Rush Medical College, of Chicago, was licensed by the Board in 1877, but that the Board subsequently revoked the license for an alleged violation of the law. A suit brought by the practitioner has resulted in a decision which practically limits the Board's power to that of the verification of diplomas and the identification of their holders, without power to revoke any license it may issue. If this decision is final, it can not but be looked upon as a severe blow to the spirit of the law, however it may accord with its letter, and is on all accounts very much to be regretted.

Vaccination Service in Spain.

The Spanish Government has issued a decree dealing with the *personnel* of the central vaccination institute of the State, which is to consist of the following officials, with salaries as indicated: One chief physician, 3,000 pesetas (a peseta is about equal to twenty cents); one physician-superintendent of visits, 2,500 pesetas; one physician-administrator and secretary, 2,000 pesetas;

two vaccinating physicians, 1,500 pesetas each; one vaccination physician, 1,000 pesetas; four physicians to visit the district, 1,000 pesetas each; one porter, 1,250 pesetas; three attendants, 750 pesetas each; and two supernumerary physicians without salary.

The Boston Water-Supply.

It is said that an idea originated by Dr. Thomas L. Jenks, a member of the Massachusetts Medical Society, has lately been brought to the attention of Mayor O'Brien and the Water Board, by which, it is thought, a great improvement can be brought about in the quality of the water. The plan is to build an open conduit, a mile or more in length, from the outlet of the system, in which large, rough bowlders are to be placed. The water, rushing swiftly over and between these rocks, will be so agitated, it is presumed, as to do away with that impurity which depends upon partial stagnation.

Items.

—The physicians of Philadelphia number 2,500. New York has about 2,900.

—Dr. Hal. C. Wyman reports an operation for congenital extroversion of the bladder of an infant five days old.

—In the *Lancet*, December 13, 1885, is reported a case in which an Enfield rifle bullet remained for more than thirty years encapsuled in the internal condyle of the femur before removal.

—In the *Boston M. and S. Jour.*, December 17, Mr. Reginald Harrison publishes a case where lithotomy was twice performed within fourteen months, with remarks on recurrence of stone in the bladder.

—Dr. Harman Leslie Snow, of Albany, N. Y., died on December 19, after a long illness. He was president of the common council, and partner of Dr. Vanderveer. He was forty-nine years of age.

—The Prefecture of the Seine has accepted a tender for the erection at the Père la Chaise Cemetery of a crematory. It is to be on the newest and most approved principles, the amount of the contract being nearly $40,000.

—In women who have much subcutaneous adipose tissue, Dr. B. Riedel advises the removal of the fat before closing the wound after amputation of the breast. The presence of much adipose tissue, he says, interferes seriously with union by first intention.

—Client (to Lawyer): "I am afraid the physician's testimony will convict me."

Lawyer (reassuringly): "Don't be alarmed about that. I'll read up a little about poison in the stomach, and in ten minutes I'll have that doctor in a cold sweat, and make the judge and jury think he is a hired perjurer."

—The *Boston Transcript* is responsible for the following:

The talk of the day: Mrs. A.—"I hear that the Montmackingtons are going to spend the winter in Paris." Mrs. B.—"Indeed? You surprise me! When were they bitten?"

—The lady secretary of the Anti-vivisection League of England argues, in a letter to M. Pasteur, that cauterization removes all danger of hydrophobia. Her son once, and she herself five or six times, have thus escaped the malady, and both offer to be bitten by any mad animal in M. Pasteur's laboratory, on condition of being allowed to treat the wounds themselves.

—A school teacher in the suburbs of Boston recently punished a pupil for telling an untruth, by putting cayenne pepper on his tongue. In the course of about two weeks he died of diphtheria. The friends of the boy naturelly claimed it to be a result of the punishment. An investigation satisfied the school committee that it was nothing but a coincidence, but they wisely passed a vote disapproving of this mode of punishment.

—The story is told in the daily press of Mme. Netalic, an actress of Paris, who has recently died, that in 1836, while playing in pantomime at the Folies Dramatiques, she had a cataleptic attack which was mistaken for death, and was placed in a coffin. Not till the first tap of the hammer on the lid did she rouse from her trance. Two years later she returned to the stage, and acted for thirty years, when she retired upon a pension. The last time she was placed in a coffin, the hammer's tap failed to rouse her.

—A reception was held at the new Manhattan Hospital, at 10th Avenue and 131st street, New York, on the evening of December 12th, and the buildings were opened for patients on the 14th. By a recent fair at the University Club Theatre, the sum of $10,000 was raised by the Ladies' Association for the institution. It is the only general hospital north of the city reception hospital at 99th street, and has grown out of a free dispensary service which has been maintained in the neighborhood for over twenty years.

JENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle pleasantly flavored. Retail $1.00. All of it pure pepsin.

HYDROLEINE

W. H. SCHIEFFELIN & CO'S.,

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*

2d. *All materials weighed with scrupulous exactness.*

3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*

4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1505- 1556

LECTURES ON INSANITY.

DELIVERED AT THE UNIVERSITY OF PENNSYLVANIA.

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Lecture VIII.

Commissions or Inquisitions in Lunacy—Traverse of an Inquisition—Voluntary Procedure for Entering Insane Hospitals or Asylums—Illustrative Cases.

Gentlemen: Let us next consider the procedure known as *interdiction*. Interdiction may result in the patient going into an insane hospital, or it may not. The person may be put simply under the control of the court, or of a guardian as a result of this procedure. Interdiction technically means that the patient is deprived for the time being of certain civil rights, not necessarily that he is put under restraint.

If you wish to protect yourself when you are in doubt as to what you should do; or when you are sure that a patient is insane, but you are also equally sure that you have no evidence with which you could make a jury believe that he is insane, the best is to advise a *commission* or *inquisition in lunacy*, by a writ *de lunatico inquirendo*. This commission or inquisition in lunacy may save you from future trouble. The responsibility is not placed upon yourself and another physician, but is thrown upon the court and the commission in lunacy. The laws of the different States provide methods by which this interdiction shall take place. In this State it is about as follows: Application is to be made to the court, to appoint a Commission before which testimony shall be taken as to the mental condition of the person. The usual plan in this city is to hear the testimony before a sheriff's jury of six persons. The person requesting the commission is represented by counsel, and the person alleged to be insane is also so represented. After the testimony is heard, the decision is made by the jury as to the sanity or insanity of the person.

Sometimes in criminal cases what might be called a "commission by courtesy" is appointed for the examination of a person alleged to be insane. Between two and three years ago, Governor Pattison requested five physicians of Philadelphia to inquire as to the mental condition of a man named McGinnis, who was in prison under sentence of death. The wording of the telegram which I received was as follows; "The Governor requests you to join Dr. Thomas G. Morton and three others in an examination of the mental condition of John McGinnis, prisoner, Moyamensing prison, under sentence of death." The same or a similar request was received by the others. The investigation was held and lasted a number of weeks. This was not a commission in a legal sense, although it was frequently spoken of as the "McGinnis commission."

Majority and minority reports were made to Governor Pattison, four of the physicians reporting that they believed McGinnis in-

sane; one that he was sane. No special action was taken, and the man was finally hanged. It has been stated that this was not a commission at all. In fact, this argument was used against the majority report being accepted. These gentlemen did not constitute a commission under the laws of the State. The fact, however, remains that the Governor, in his official capacity, had asked these five gentlemen to investigate the case of this man under sentence of death, and after doing so had refused to be guided by the decision of four out of five. Indeed, although they gave, without pay, much time and labor to the investigation, he even forgot to thank them.

A short time before Joseph Taylor was hanged, during the present year, an effort was made to have a commission appointed to investigate his mental condition, but the Governor refused to accede to the request made by counsel for the prisoner. Taylor had been convicted of murder in the first degree, after a vigorous defense on the plea of insanity. In the trial of the McGinnis case, the defense of insanity was not made, but the counsel endeavored to secure a verdict of murder in the second degree on the ground of intoxication. In the Taylor case the prisoner was convicted, and a new trial was refused. The case was taken to the Supreme Court, but without avail, and the prisoner was finally sentenced. His counsel, still believing in his insanity, and having further evidence of it, in his conduct subsequent to his sentence, made the request above-mentioned of the Governor. Taylor's counsel had spoken of the McGinnis case in their request. The Governor, in his reply, said, "You are in error in regard to a commission in the McGinnis case. The gentlemen appointed to inquire into certain statements made relative to the unfortunate man, resolved themselves into a 'commission.' They held no authority for such procedure from me. Your application for executive clemency should be made to the Board of Pardons." So far as I know, the physicians referred to never made any claims as to their powers. The Governor, in writing to them, sometimes addressed them as a "commission."

It is a grave defect in our laws if there is no provision by which something can be done to determine a man's mental condition, after he has been sentenced for murder or other crime. In the McGinnis case every procedure possible was adopted. Practically we are in this position in Pennsylvania; a man sentenced to death may have this sentence hanging over him for several months, or even years, and may be or may become insane, and overwhelming proof may be ready to be adduced, yet nothing can be done save a simple application to the Board of Pardons. No scientific investigation which will have any legal weight can be made. Later I will speak of another form of Commission.

Is the decision of such a commission under the laws of the State final? No. The insane individual is still protected in this respect. Even after the decision of such a commission has been rendered, there are two or three ways in which the person alleged to be insane can appeal his case for further consideration.

The new lunacy law provides that the report of the inquisition in lunacy shall be sent to the committee on lunacy. This committee visits the patient and examines his mental state. It has the power to revoke what has been done and again bring the matter before the court.

Another legal procedure may be adopted, and this was resorted to recently in this city in the celebrated "Meredith case." This is what is known as a traverse of the inquisition. The person who has been decided to be insane by an inquisition, can employ counsel and traverse the inquisition. He can go into open court, before a jury of twelve men, and have the whole question as to his sanity or insanity tried over again. Just as likely as not he will get a verdict in his favor.

The traverse in the Meredith case was tried in this city in 1883. This case will eventually go into the annals of medical jurisprudence, for it involved many questions of legal and medical interest. I shall at this time refer to this case only with reference to traverse procedures.

Meredith is the son of a distinguished jurist and statesman, himself a lawyer by profession. He was alleged to be insane. The insanity was supposed to have existed for a number of years. A number of years before he had been sent to an asylum, from which he was discharged as the result of a suit on a writ of habeus corpus. He was given his liberty and remained at liberty for a long time. He showed evidences of insanity, or what were supposed to be evidences of insanity. Physicians were called in several times. I saw him in connection with Dr. William Hunt, and upon a certificate of insanity signed by Dr. Hunt and myself, he was sent to the Pennsylvania Hospital for the Insane.

While he was in the hospital, some of his relatives brought action before a commission in lunacy to settle, if possible, the question whether or not he should be legally restrained. The commission sat and the jury decided that he was insane. Testimony was given by Drs. S. Weir Mitchell, Ellwood Wilson, S. Preston Jones, R. A. Given, Wm. Hunt, and myself. He was adjudged insane, and recommitted to the hospital.

The case was then brought before the court by a traverse of the inquisition. Mr. Meredith was represented by two of Philadelphia's most distinguished lawyers, Richard P. White and Daniel Dougherty. The trial lasted four or five days. The same gentlemen who had testified before the commission again gave testimony. Witnesses were called for the other side, but not a single medical witness could be induced to testify to the sanity of the unfortunate gentleman. The effort was made to secure medical witnesses to testify as to his sanity. One physician called upon for his opinion said that he believed Mr. Meredith to be insane, and that the only way for the lawyers to win their suit was to blackguard the doctors fron beginning to end. The lawyers largely followed this advice, and did win their suit; so that from a legal point of view, at least, it was good advice. Whether it was right in other respects I shall not say. The case was argued, and went to the jury, and in a few minutes the jury declared the man to be sane, although, perhaps, the Philadelphia courts have never known a case in which the facts showing insanity were more clear, convincing, and uncontradicted.

I shall next speak of the voluntary act by which a person can place himself in an asylum or under restraint.

Section 34 of the Pennsylvania lunacy law of 1883 is as follows: "Persons voluntarily placing themselves in any of the houses provided for in this act, may be detained for the time they shall specify by an agreement signed by them at the time of their admission, but not exceeding seven days, and they may from time to time, renew the authority to detain them for a time not exceeding seven days from such renewal. But no agreement shall be deemed to authorize a detention unless signed in the presence of some adult person, attending as a friend of the person detained, in the presence of and also by the person in charge of the house, or the medical attendant."

The patient, just referred to, took advantage of this act of voluntary admission, after he had been declared sane by a jury under a traverse of an inquisition. He voluntarily sought the shelter of the very institution from which the law had set him at liberty, and he has since remained as a voluntary inmate of this or some other institution.

This provision for voluntary seclusion is, I believe, not infrequently taken advantage of by inebriates. Those in charge of institutions are compelled to be careful that the strict requirements of the section are carried out. If the patient remains more than seven days, they must see that the agreement is renewed again and again, and that the proper witnesses are present at the time renewal is made.

Communications.

CONTRACTIONS OF THE EXTERNAL AUDITORY MEATUS.

BY LAURENCE TURNBULL, M. D.,
Of Philadelphia.
Aural Surgeon Jefferson Medical College Hospital, etc.

Contractions of the external auditory meatus are caused by infiltration of its lining membrane, by cicatrization after diseases of the ear, as chronic eczema, etc., injuries, burns, or by exostosis, and hyperostosis and new osseous formations in the walls of the meatus.

In a few instances the contraction is congenital, as in many cases we have seen, in which there is not an entire absence of the auricle or external ear, but it is a rudimentary state. The case of a little patient only nineteen months old; otherwise a fine, large child of his age; general health good. The child was born of healthy parents. The presumed cause given was that the mother, during pregnancy, was frightened by a dog. It will be noticed that there are but three rudimentary portions of the auricle, the two upper being projections of cartilage, and the lower one having a curved appearance. There is no lobule, and in the space where the concha and meatus are usually found, is a plain surface, covered with skin, the auditory canal being wanting. There seems to be a depression in the locality where the meatus should be; this is the cicatrix after an attempt to open the tube, a circular piece of tissue having been cut out, but the space was persistently filled up. The tragus is entirely wanting, therefore there was no guide to the operation, although the physician, a very intelli-

gent one, who sent the case, thought that he could feel the cartilage which formed it, but I was not able to do so. On testing the child's hearing for that (the right) ear, it was noticed that when the watch, a very loud ticker, was placed near to but not touching the ear, his eye brightened, and he looked as if he heard; the same result was noticed with the tuning-fork, even when the face was turned from it.

When you examine little children for hearing before they are able to talk, you can never arrive at a positive conclusion in regard to it, you will have to rest satisfied with an approximation; and this was all I could do in this case. It is sometimes one of the most painful duties which a physician has to perform to decide and state the fact that the child is absolutely deaf; the parents and friends of such children often deceive themselves with the idea that the child hears, when loud noises of various kinds are noticed by the child, which is usually the result of simple concussion and vibration of the air or floor. When testing such cases, the eyes of the child on which the experiment is made should be turned from the cause of such noises. To be absolutely sure, it is well to test the hearing in the dark, but by no means allow the child to see the watch, tuning-fork, bell, etc.

The prognosis in this case, therefore, was very guarded, the only favorable feature being the hearing on the right side, when the opposite ear was carefully closed. After the removal of a curved-shaped piece of skin, connective tissue, etc., the probe was introduced and sunk into a depression of half an inch, but no cartilage or bony meatus was found; this opening was then filled with patent lint saturated with carbolized olive oil, and every means taken, for thirteen days, to keep the parts open.

The parts being healed and filled up, the little patient was again placed under the influence of the anæsthetic, the parts freely opened, and a leaden tube was made to fit the opening. A letter was directed to the physician who sent the child to try to keep the parts open. This was conscientiously performed, but with all his care the parts filled up, leaving but a depressed cicatrix.

Now, what is to be learned from the history and the operation in this case? First, it is proved that there was no cartilaginous portion beneath the skin forming the auditory canal. In such cases, where there is an entire obliteration of the meatus externus, there has been found by careful dissection an absence of that portion of the temporal bone which forms the tympanic ring, and the lower side of the bony canal of the meatus; and the extension backwards of the articular and true glenoid portion of the temporal bone is twice its natural breadth. The next class is a cutaneous closure of the external meatus, and with such there is sometimes a contraction of the osseous walls, which may be relieved by opening the canal with the knife, and subsequent dilatation by oiled lint, compressed sponge, or bougies of laminaria; in this way we have restored the hearing of more than one patient. The parts, however, are so apt to contract that it may be, and sometimes is, necessary to fill up the auditory canal with a gold or nickel-plated funnel-shaped tube until the parts heal. On examining the left ear in another case, we find that where the auditory canal should be the place is covered by a smooth skin; in every other part the ear, although smaller, is almost perfect, and her hearing is almost the same (good) in both ears. Her mother stated that the cause of the deformity was owing to a child having slept with her, and having placed its foot on her (the mother's) ear, she was suddenly aroused from her sleep by the strange feeling, and supposed it to be a rat. By means of a crucial incision and the use of the leaden tube, the meatus was restored in this case.

Another class of cases is where there is narrowing or closure of the external auditory meatus by tying cap-strings or ribbons behind the ears. A case is of an old lady where there is nothing but a slit, caused by the constant pressure of cap-strings passed behind her ears and tightly tied under the chin. This is the form of contraction of the cartilaginous meatus where all the secretions are retained, and produce deafness and chronic eczema of the meatus, with an accumulation of cerumen, epithelium, etc. This variety requires repeated and careful syringing, to keep the ear clean, thorough drying of the parts, and sometimes a quill or metallic tube to keep the walls of the meatus from collapsing.

We still have another variety in which the canal becomes more or less obstructed by *ostosis, or bony growths*, and this from retained secretions, or by pressure, causes deafness, and serious trouble also. These growths are sometimes removed by means of a perforator or hand-drill. The continuous galvanic current has also been applied after the removal of any skin covering; two or three needles may be used, and perhaps passed into the bony mass after first drilling with a hand-drill. The application of the

current may be made under the influence of ether and painting the parts with four to ten per cent. solution of cocaine, to be repeated from three to five minutes for a succession of days until the bone is separated. A galvanic battery is usually employed, the number of cups brought into the circuit being from ten to thirty. It usually requires two weeks of treatment. Where there is simply uniform closure of the bony meatus without distinct rounded masses, or ostophytes, they are also removed by means of the dentist's drill. Care, prudence, and caution, however, are important in employing such violent measures for the relief of those congenital and acquired closures as inflammation is almost sure to follow, and in one case such a result was induced, and with it facial paralysis of that side.

There are two diseases in which contraction of the cartilaginous and osseous meatus occurs; the first is during and after chronic otorrhœa; the second disease in which it occurs, although more rarely, is non-suppurative inflammation of the middle ear, and in both the result of inflammatory action accompanied by hypertrophic formation tissue or bone, or both, and occurs as well throughout the whole petrous portion of the temporal bone. This form of closure is termed hyperostosis. Gout and syphilis are considered by most authors to be the causes of these exostoses.

I have reported cases in my "Manual of Diseases of the Ear,"* where, in one, there were three enlargements of the bone projecting into and almost completely closing the meatus which was improved by treatment with the solid nitrate of silver, etc. Another case was operated upon by narrow chisels applied directly to the base of the exostosis with previous incision of the skin, and it required strong blows with a wooden hammer to remove it. The case did well after the acute inflammation had subsided and the granulations had been reduced. The patient was left with a good-sized meatus and fair hearing after protracted local treatment.

A still more recent case was treated successfully by the use of the laminaria tent charged with boro-glyceride ointment. The mass was of a conical form, looking like a polypus, and was the result of acute inflammation. It required very prolonged treatment by various agents, and the constant use of laminaria tents, but ultimately the patient recovered, so as to give him a sufficient space for the sound ($\frac{1}{8}$ in.) to enter, and his hearing was restored.

A very interesting case is reported by Dr. Clarke* of a cure of a large exostosis, completely closing one meatus by means of electrolysis—the diagnosis and the cure being affirmed by Mr. Hinton.† At the first sitting under chloroform, two needles attached to the negative pole were inserted at the base of the tumor, and one needle attached to the positive pole at the anterior edge. A current from six pairs of plates of a Stöhrer's battery was allowed to pass for three minutes. No irritation or pain followed. Fourteen days after, under chloroform, two needles with similar attachments were used for five minutes. No ill effects followed this application, and the tumor was somewhat reduced in size. Three weeks from this time, on examination, the exostosis was found to be loose, and was removed entire. The attached surface where the needles were inserted was seen to be absorbed by a mere point, and this point had broken off.

A case was reported by Dr. Green,‡ of Boston, which was under his observation both before and after treatment, it was operated upon by Mr. Dalby, of London, in the same way, but the result was less fortunate. A polypoid growth behind the exostosis with symptoms of cerebral irritation rendered the operation necessary. The various details of the operation he did not know, but the patient said he suffered extremely from acute inflammation of the ear for some days after the operation. As the result either of the electric current or of tympanic inflammation, the facial nerve on the affected side was paralyzed. When Dr. Green saw him some four months after the operation, the exostosis had entirely disappeared. The meatus was normal, the old purulent tympanic inflammation had subsided, and the result was a most perfect one, except for the unfortunate accident of the facial paralysis, which remained without improvement. Mr. Dalby§ considers that the tympanic inflammation extended to the Fallopian canal, and thus caused the paralysis of the portio dura, for if it had been due to the electric current, it would have occurred immediately, whereas it did not show itself till the next morning. Since this Mr. Dalby‖ prefers the operation of grinding the bone away, and for this pur-

‖Op. cit.

pose uses the drill in common use among dentists.

Mathewson* was highly successful in the removal of a large exostosis by means of the so-called dental engine. The instrument used was an Elliott's suspension dental engine, with drills of three sizes. The patient was etherized, the integuments covering the exostosis removed by a dental scaler, and the growth perforated at several points with the smallest drill—one and a half millimetres in diameter. These perforations were then enlarged and united by the larger drills —two and a half and three millimetres in diameter—and the irregularities ground away. The operation lasted some twenty or thirty minutes.

The pain afterwards was easily relieved by warm-water douching and small doses of opiates. Purulent discharge, with swelling and granulations at the seat of operation, continued for some weeks, but finally ceased entirely, leaving a meatus of full size through which the membrana tympani was seen. The hearing was restored nearly to the normal standard.

The advantages of the dental engine over the other method of operating, Mathewson says, are that it is less tedious from the rapidity of its revolutions, and less dangerous in that the rapidity of its motion perforates with slight pressure, and the risk of slipping and injuring important parts of the ear is very much diminished.

It must not be supposed that all the cases you meet with can be successfully cured or even relieved, especially that variety of exostosis with a broad base.† Another variety it is very difficult to relieve, namely, that form in which the whole bone is involved and the orifice is so small as not to admit the finest probe. There are so few cases in which the bony growth is a simple spur in the centre of the meatus not attended with much deafness; this class of cases I do not operate upon. Death will sometimes follow from meningitis in certain classes reported by Dr. Green, of Boston, as follows: "Exostosis in connection with a secreting tympanic inflammation, either catarrhal or purulent, must be regarded as a serious complication, for the case first reported in this paper is a demonstration of the fact that such growths, although quiescent for years, may suddenly increase so as to close the meatus and produce the results of retained pus. In these complicated cases there is not only the risk of the exostosis closing the meatus, and so producing a caries of the bone, but if the growths have attained merely a moderate size they so obstruct the view of the deeper tympanic cavity, that it is often impossible to make the applications to the tympanic mucous membrane, which are necessary for relieving the otorrhœa. From these two circumstances, the possible closure of the meatus, and the constant obstruction to the treatment of the otorrhœa, the removal of the growth is distinctly indicated; it is certainly imperatively demanded whenever they are associated with an otorrhœa, and are also known to be rapidly increasing in size."

Of the cases above-mentioned, one had no recollection of ever having suffered from any kind of inflammation of the ears, and I saw him on account of an entirely closed or narrowing meatus. The other four cases were in persons suffering at the time from chronic purulent inflammation of the tympanum, with more or less destruction of the drum-membrane and great impairment of the hearing; the exostosis existed only in the inflamed ears, and in each but one ear was diseased.

Exostoses of the meatus have been found both in South and North American aborigines. In an examination of fifty Peruvian skulls, one was found in which exostosis filled up the lumen of both meatuses. Whether these anomalies depend on certain race peculiarities, or on the mechanical irritation of the meatus, caused by wearing heavy ear-pendants, has not been yet determined. The most frequent place in which the exostoses are found is the union of the osseous with the cartilaginous section and the posterior wall of the meatus.—*Boston Medical and Surgical Journal, April*, 1878.

*Report of International Otological Society, 1876.

† In a successful removal of an ivory exostosis which completely filled the ear canal, Dr. Knapp "no longer attacked the tumor, but the tissue in which it originated, chiselling into the bone of the ear canal." When the operation was completed, the whole posterior wall of the canal was bare. During the operation the canal was frequently syringed with a warm solution of boric acid, and wiped out with absorbent cotton. When the hemorrhage was arrested, some boric powder was put in the canal and covered with absorbent cotton. Iodoform was put into the canal eleven days after the operation. The headache from which the patient suffered was still present and in front of the wound rough bone became the starting point of vigorously spouting polypi, which had to be scraped away, every three or four days, but by the use of a four per cent. solution of cocaine dropping upon the granulations the removal of the granulation, head bone, etc., was almost painless, and in six weeks the patient was free from the headache, and ultimately recovered. Archives of Otology, vol. xiv., Nos. 2 and 3, 2123, June and September, 1885.

THE TREATMENT OF PELVIC ABSCESS IN WOMEN BY INCISION AND DRAINAGE.*

BY PAUL F. MUNDÉ, M. D.,
Of New York.

The author drew the following conclusions:

1. Pelvic abscess in the female is not very common in proportion to the frequency of pelvic exudations. It probably does not occur in more than ten per cent. of all cases. The majority of cases terminate in spontaneous absorption of the exudate.

2. Pelvic abscess may be extra-peritoneal, most commonly the result of pelvic cellulitis, or it may be intra-peritoneal, the result of pelvic peritonitis. The adhesions in the latter case might make the abscess practically extra-peritoneal. Abscess of the ovary and pyosalpinx did not fall into the division of pelvic abscess proper.

3. In small, deep-seated pelvic abscess, not containing more than two ounces of pus, and in multiple abscesses of the cellular tissue, a permanent cure might be effected by simply evacuating the abscess cavities with the aspirator.

4. About one-half of the abscesses open spontaneously into the vagina, rectum, or pelvic or abdominal wall. These abscesses may heal spontaneously, or they may require surgical interference.

5. Abscesses containing more than two ounces of pus should be opened by free incision, cleared of debris, and drained, if necessary, through a drainage-tube.

6. This incision should be made at the point where pus points most distinctly, usually in the vagina.

7. In a certain number of cases pus points in the abdominal wall, usually at the iliac fossa; and here the drainage-tube would be required.

8. In some cases in which the pus burrowed deeply into the pelvic cavity it would be advantageous to make a counter opening through the vagina, and establish through drainage from the abdominal wall into the vagina.

9. Opening a pelvic abscess which points in the abdominal wall does not differ from this procedure in other cases, and is not attended by greater danger when adhesions have taken place.

10. Chronic pelvic abscess—abscess bursting spontaneously and discharging through the vagina, rectum, and elsewhere—might exist many months or years, and prove exceedingly difficult to cure; this is particularly the case when it opens high up in the rectum. A counter-opening should be made in the vagina, for Dr. Mundé doubted the propriety of enlarging the rectal opening even if it were possible to reach it.

11. In doubtful cases, aspirate and establish the diagnosis.

12. The majority of cases of pelvic abscess will recover.

PROLONGED ANÆSTHETIZATION BY INCARCERATION OF THE ANÆSTHETIC FLUID IN THE FIELD OF OPERATION.*

BY J. LEONARD CORNING, M. D.,
Of New York.

The fluid employed was solution of hydro chlorate of cocaine. Dr. Corning first mapped out the course of the veins, rendering them prominent by a moderately tight rubber bandage on the limb, which obstructed the return circulation. He then rendered the limb bloodless by means of an Esmarch bandage. The injection was made very superficial at first, to avoid pain from the needle, and after partial anæsthetization, the extent of the injection could be enlarged. Before sufficient time had elapsed for the fluid to be carried away into the general circulation, the tourniquet was applied at the upper edge of the anæsthetized zone, thus incarcerating the liquid in the field of the operation. If the tourniquet could not be employed on the part operated upon, he made use of hæmostatic rings. By making pressure upon these the circulation could be markedly decreased in the part injected. This method had now been employed by a number of physicians and surgeons in this city, who would testify to its excellent effects. A one, a one-half, a one-third, and even a one-fifth per cent. solution of hydrochlorate of cocaine was sufficiently strong to produce local anæsthesia by this method. But a one-fifth per cent. solution was not reliable. A one or a half per cent. solution was usually preferable.

—The vaccine from revaccinated children is of doubtful protective potency, according to the observations of M. Blot, recently reported to the *Academie de Médecine.*

Hospital Reports.

CHILDREN'S HOSPITAL OF PHILADELPHIA.

Service of Dr. John Ashhurst.

Arthritis of Knee.

This little boy, aged ten years, fell from a swing, striking his right knee on a stone. He did not complain at the time, and his family had no idea that he was hurt until they noticed that he walked lame. His parents are healthy, and an inquiry into his own medical history only reveals that he had measles when quite young and scarlet fever a little more than a year ago, but there were then no joint sequels. He was in another hospital for seven months, where the joint was aspirated and half an ounce of pus withdrawn; after which, tincture of iodine was used locally for some time, and subsequently equal parts of belladonna and mercurial ointment were applied to the knee, and the limb was encased in plaster-of-Paris. He was given internally liquor ferri iodidi.

Under this treatment, the circumference of the knee diminished about one and one-half inches. When he entered the Children's Hospital, the joint was enlarged, there was but little, if any, increase of heat, and the joint was not painful. The movements were diminished, there being a tendency to anchylosis. Tincture of iodine was used locally and a plaster splint applied. After about three weeks the splint was removed, and the knee was found inflamed, which, it was supposed, was due to the iodine. He was put to bed and lead-water and laudanum used. Five days later the inflammation was entirely gone, when a posterior splint was applied and he was kept in bed.

Subsequently, the knee was covered with soap plaster and pressure made by a tight bandage. He continued steadily to improve, and was discharged very much relieved.

Fracture of the Femur.

A gate fell on the right thigh of this boy, who is only three years old. One hour later, he was admitted to the hospital. The thigh was flexed on the abdomen, the leg on the thigh, and there was much swelling at the seat of injury. Long and short splints were applied, with sand-bags and a stirrup extension apparatus. Four weeks later the splints were removed and a splint of binders' board adjusted. Two weeks later he was discharged with perfect use of his limb.

Arthritis—Excision of Knee.

This boy, thirteen years old, fell from a shed, six months before his admission, and struck his left knee on the ground. Three months later he had scarlet fever, and from this period the knee became so painful that he was confined to bed, and the joint became anchylosed. After the joint became fixed, the limb being at an obtuse angle, he was able to walk about on crutches. His general condition was fair. Dr. Ashhurst performed excision of the knee-joint; there was very little hemorrhage, and six weeks after the operation the boy was discharged, with a straight leg.

Infantile Paralysis—Lateral Curvature of the Spine, etc.

At six years of age, this little girl (now 9) had "brain fever," after which there was manifested sudden and almost complete paralysis of both the upper and the lower extremities, so much so that she could move neither fingers nor toes. Afterwards there was some improvement, and she seemed to be getting slowly better. When admitted to the Children's Hospital she was large for her age, and her general appearance was good, but she cannot stand without supporting herself on the back of a chair. She has fairly good use of her arms and hands, while the legs are almost useless. There is also quite marked lateral curvature of the spine. A plaster jacket had been put on seventeen months before, and had not been removed since. It was now taken off, and no excoriation or maceration of the skin was noted. There was found decided curvature, with the ribs projecting on the right side, at about the junction of their middle and posterior thirds, while the left side was much flattened behind and prominent in front. She was suspended and a fresh plaster jacket applied. The constant electric current was then commenced on the limbs. Two months later it is noted that for some days past there has been considerable ulceration of the buccal mucous membrane, which has improved under the use of a wash of borax. Becoming again sore, the ulcers were touched with nitrate of silver, all solid diet was interdicted, and she was kept on beef tea and milk. Six months after admission, she had German measles and catarrhal conjunctivitis, for the latter of which borax (gr. x. to f.℥j.) was used, and later nitrate of silver (gr. j. to f.℥j). The eyes continuing to grow worse, the silver was stopped and atropia (gr. iv. to f.℥j.) was used with the borax wash. The left ear now began to discharge, and upon examination it was found that the membrana tympani was ruptured. The girl got along well, and was discharged much improved in all respects.

Membranous Croup—Tracheotomy.

A boy, aged three years, was admitted, suffering from membranous croup, which he had had for six days, but it had not assumed a severe form until two days before admission. His respiration was laborious, surface cyanotic, and presenting all the symptoms of a very severe attack. His parents are healthy, though the mother has a tendency towards a strumous diathesis. The child is large and well nourished. Tracheotomy was performed, shortly after which some of the membrane was coughed out, which brought great relief. During the following night he slept considerably, and all the symptoms were improved. He was ordered

℞.	Tinct. ferri chlor.,	gtt. v.
	Pot. chlor.,	gr. v.
	Syr. simpl.,	f.℥j.

To be taken every three hours.

The next day it is noted that there was much uneasiness throughout the night; he takes his food well, and is bright. The ward is kept at a temperature of 80°, and a vessel of water kept all the time boiling on the stove. The boy is covered with a double blanket, and flannel is placed about the chest, while gauze is laid over the tracheotomy tube to prevent the ingress of foreign matter. For a couple of days the tube is cleansed (with a feather) every three hours. He sleeps well, and takes plenty of liquid diet. The temperature never exceeded 100⅖°, and ten days after the operation is 99°. There is some little irregularity of the action of the heart. Eight days after the operation he is allowed some oatmeal, chicken, and mashed potatoes. Seventeen days after the operation the tube is removed, but there is so much obstruction to respiration, that it is put back; the same experience is had the succeeding day. Eleven days later he is able to be out of bed for three or four hours at a time without undue exhaustion. The above medicine is now stopped. Four days later, he can keep the tube out for a few minutes, but soon becomes strangled, and it must be put back. He can talk out loud with the tube in, sufficient air passing around the tube. Three days later, there was a spasm of the larynx, lasting about ten minutes, when the tube was removed, and the body became cyanotic. This condition was not relieved when the tube was replaced, but it rapidly disappeared when he was put to bed. Six days later the temperature of the ward was let down to from 70° to 72°, and the boiling water dispensed with. Four days later the tube was permanently removed, and shortly thereafter the wound was so nearly closed that an ordinary probe could hardly be introduced. Two days later (it was cold) he was a little croupy, when he was put to bed and kept there until it became warmer. Eight days later he was discharged cured, with the wound entirely healed.

Five days after this boy was discharged, tracheotomy was performed on another boy, aged five years, and he died in a few hours.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Prof. Parvin.

Prolapsus Uteri.

This woman presents a tumor, and it is for us to find out its nature. She has had several children, and her menses are regular. This tumor projects from the vagina and protrudes between her thighs, and it recedes when she lies down. She has difficulty in evacuating her bladder, but when this is accomplished, the tumor subsides somewhat. The tumor is four or five inches long, and there is a laceration of the perineum. It is very easy to diagnose this mass as a prolapsed uterus. No pessary will give any relief worth mentioning. The woman must be operated upon; the perineum restored, and after amputating one-third of the uterus, replace it.

Probable Ovarian Tumor.

This woman, aged forty-nine years, has had a tumor or swelling of the abdomen slowly increasing in size for seven years. She has not menstruated for seven months. The tumor is nearly symmetrical, In order to get the best idea of the symmetry of a tumor, you should expose the abdomen and stand at the foot of the bed, looking up at it. It is slightly more prominent on the right than on the left side. This might be a pregnancy. We will look for changes in the circulation. Enlarged veins in the abdomen are of no use in the diagnosis of an ovarian tumor unless they are confined to one side. The most common form of enlargement of the abdomen, outside of pregnancy, in a woman, is an ovarian tumor. Ascites may be confounded with ovarian tumor. If this were ascites, the fluid would bulge the abdomen out on the sides and the swelling would not rise up in the median line as it does here. If ascitic the greatest circumference of the abdomen would be found at the umbilicus; in this case it is below that point. In both cases the measurements from the pubic symphisis to the umbilicus and from the umbilicus to the sternum would be increased, but

their relation to each other would not be materially altered in ascites, whereas in ovarian tumor the lower measurement would be much more increased than the upper. In this case the difference between them is three inches; ordinarily it is only about one. This woman measures thirty-one and one-fourth inches around the abdomen at the umbilicus. If ascitic, there would be clear resonance on percussion at the upper part of the tumor, because the intestines would float on the surface of the liquid; but if it were ovarian we would have dullness, as the tumor would directly approximate the walls of the abdomen. If it were ascitic, there would be dullness in the flanks, and the air sound would vary with the position of the patient, the intestines always floating to the highest point. This might be a fibroid or a fibrocystic tumor of the uterus. While somewhat hard to the touch, it is not quite the hardness of a fibroid. There is some dullness here on the left side. We can produce fluctuation in this mass, which proves that it is fluid. This tumor moves noticeably on respiration. In fibroids, we usually have a history of disturbed menstruation, which we did not have here until very recently. In fibroids, also, we should have some enlargement of the uterus. He places the woman in "Sims's left lateral position" (on her left side, with the arm behind her, and the right knee thrown over the left), introducing a speculum, and passes the sound, using a tenaculum to pull down the uterus. He finds the uterus not enlarged. Dr. Parvin dismissed this case by telling the story about the French academician, who, upon being asked a question in science by a lady, replied that he did not know how to answer it; upon the lady asking him what was the use of being a member of the academy if he could not answer it, replied that this membership gave him the right to admit his ignorance. Applying this anecdote to himself, Dr. Parvin said that while he was strongly inclined to regard this as an ovarian tumor, yet he was in some doubt, and would make further examinations before he formed a positive opinion.

Enlargement of the Ovary.

This woman, single, aged 31, complains of great pain in the region of the ovary. In order to locate this pain, we must grasp the ovary, which can be seized between two fingers in the vagina and two fingers pressing down into the abdomen. This is rendered especially easy if the womb happens to be anteflexed. When examining on the right side, we should use two fingers of the right hand in the vagina and on the left the left fingers. If then the two fingers are passed into the vagina, and the abdominal wall is not too tense, we can feel the ovary midway between the pubic symphisis and the anterior superior spine of the ileum. He feels the ovary, enlarged to the size of a walnut, and notes that it is very tender on pressure. The uterus is also here enlarged. The discomfort can be relieved and the enlarged ovary perhaps reduced by the use of glycerine tampons and the application of iodine to the vagina. If we put a solution of iodide and of iodate of potassium on one piece of cotton and a solution of citric acid on another, they will both be colorless; but when we bring them together, the pure iodine is deposited on the cotton and we have its characteristic color. If then we apply these two preparations, one after the other, to the vagina, we have the crystals of iodine deposited just where we want them.

PHILADELPHIA HOSPITAL.

Service of Dr. W. H. Parish.

Diagnostic Signs of Pregnancy.

Dr. Parish is demonstrating practically to the class the signs of pregnancy. Here is a woman within two weeks of labor with her first child. The breast is very large and we have the usual signs. The external os is not transverse (as we find it in multipara) but circular. There is an apparent shortening of the neck of the uterus, which is due to a swelling of the upper portion of the vaginal tissue. There are regular periods of congestion of the uterus during pregnancy, corresponding to the menstrual periods, and at such times, if there is any abnormal condition of the organ, ulceration of the cervix, etc., we may have bloody discharges that simulate menstruation. A woman usually feels the quickening at the fourth month, though Dr. Parish has a patient who has had several children, who can detect it as early as the third and even at two and a half months. The action of the recti and oblique muscles may deceive us unless we are very careful when feeling for the movements of the child; especially is this so in the case of hysterical women, who for various reasons desire to be thought pregnant. The day is cool, and Dr. Parish has, for some time, been handling the abdomen with his cold hands. He now tells us that he has done this for a purpose. He found the uterus somewhat flaccid, seeming to want tone; his manipulation has rendered it tense. Such a proceeding will sometimes

aid us in the diagnosis of an extra-uterine pregnancy; for if the product of conception be not in a muscular bag like the uterus, no amount of cold friction will render the tumor tense. Ballottement is only valuable during the fourth, fifth and sixth months; before that the child is too small, later it is too large. An extra-uterine pediculated fibroid tumor will sometimes strongly simulate pregnancy. The fœtal heart-beat (usually discoverable about the twentieth week) is generally about double that of the mother, ranging from 120 to 160. He recently examined a woman and heard a pulsation in the abdomen of one hundred and twenty per minute; he was about to consider her pregnant, when he felt the pulse in the wrist and found that it was also one hundred and twenty; it was a transmitted aortic sound he had heard. Be careful, therefore, always to compare the pulse heard in the abdomen with that of the woman at the wrist. In this case he listens in all positions, but can hear no fœtal pulse, the abdomen is quite fat, which probably accounts for it. The sounds are usually heard in the course of a line drawn from the umbilicus to the anterior superior spinous process of the ileum. They can be heard better when the back of the child is forwards, because, then, it lies directly against the wall of the uterus, while if this position is reversed, the flexed arms and legs keep the surface of the child away. There is no such thing as a *placental* bruit, still frequently described in text-books. In 1822 this sound was first noted and supposed to be produced in the placenta, and was so named. But it is erroneous; it is really a uterine bruit. It is a blowing sound, as is produced in enlarged vessels, in aneurisms, and it is best heard over the sides of the uterus where the enlarged vessels are situated. Early (about the fourth month) it can be heard in the median line, above the pubes, but when the womb grows larger, it is heard low down in the abdomen and to the sides. A strong proof that it is not placental is the fact that it can be heard for several days after labor and the removal of the placenta. If it were of placental origin, it would possess great diagnostic significance, as, for example, in the detection of placenta prævia, hence, since it is not so produced it is important that this fallacy should be corrected. This bruit may be heard in the case of a fibroid tumor, produced by the enlarged blood-vessels in the hypertrophied uterus, and it may also be heard in marked sub-involution, even for months after labor. A funic souffle is heard in the cord, corresponding to the fœtal heart-beats. Sometimes we may not be able to hear the heart-sounds, and the child may not move under our manipulations, when we are apt to think that it is dead, when such is not the case. When death does occur, the abdomen commences to shrink, if there has been a souffle, it disappears, the uterus becomes more flaccid, loses tone, and "tumbles in," as it were. If the finger can be passed into the womb, and the fœtus is steadied from above, the bones of the head will be movable, if the child is dead, there is a want of tonicity; this symptom alone has caused Dr. P. to suspect death in several cases when he was subsequently proven to be correct. To determine the date of expected labor, count back three months from the beginning of the last menstruation and add seven days to that date.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated meeting, December 10, 1885. The president, J. C. Wilson, M. D., in the chair, W. E. Hughes, M. D., Recorder.

Dr. G. E. de Schweinitz presented a tumor of the testicle. Eighteen months before the first evidences of enlargement of the testicle, the patient had contracted syphilis. This led to a diagnosis of syphilitic disease of the testicle, but the steady progress of the enlargement, in spite of specific treatment, soon compelled a change of diagnosis with a consequent removal of the organ. One month after this removal the patient died, with recurrence in the abdomen. Microscopic examination of the growth showed a stroma of young spindle cells, interspersed with variously-shaped collections of cells closely resembling cancer-cell nests. The seminiferous tubules are normal, or their cells are in active proliferation, or have passed out into the surrounding tissue to help form the nests mentioned.

Dr. H. R. Wharton presented a specimen from a case of gelatiniform arthritis of the knee-joint. The joint had been diseased for two years, and was excised by Dr. John Ashhurst, jr. In addition to the usual signs of the disease, the specimen showed a circumscribed patch of caries in the external condyle of the femur.

Also, a larynx and trachea from a case of membranous croup, in which tracheotomy had been performed. The patient, a girl, æt. four years, had had croup for some days

when increasing dyspnœa necessitated tracheotomy. After a period of relief, she died suddenly. Post-mortem examination showed a complete membranous cylindrical cast of the larynx and trachea, extending into the larger bronchi. There was also an ante-mortem heart-clot. The exhibitor remarked that the points of greatest interest to him were the great relief following the operation, although there was much membrane below the point of opening, showing that the dyspnœa was due, to a certain extent, to reflex laryngeal spasm; the extreme smallness of the trachea; the extensive deposit of membrane, and the fact that the trachea tube might easily have been pushed between the membrane and the inner surface of the trachea.

Dr. Carl Seiler thought that in these cases of croup, as well as in cases of foreign body in the larynx, it was a reflex spasm, rather than the direct obstruction, that caused the dyspnœa. He had found that it is not inspiration that is interfered with, but expiration; this would lead to the conclusion that the interference is due to spasm. Now, if it is principally spasm, intubation of the larynx might in some cases supplant tracheotomy; it might at least be tried before tracheotomy is resorted to.

Dr. Wharton thought that in movable foreign bodies it was the expiration that was most interfered with, while in an impacted foreign body, or in an exudation, it was the inspiration; this he had been accustomed to regard as a diagnostic point.

Dr. J. B. Deaver presented a congenitally misplaced right kidney, taken from the body of a subject in the dissecting rooms of the University of Pennsylvania. It was situated opposite the fourth columnar vertebra, resting upon the aorta and common iliac arteries and veins. It derived its blood supply from the aorta and common iliac by two arteries. The two veins emptied into the ascending vena cava and common iliac. The ureter sprang from the anterior surface and entered the bladder normally.

Dr. H. A. Hare presented a patient with an anomalous hand, a negro, æt. 45 years, who had a supernumerary little finger on each hand. Each finger has a nail, and is fairly well formed, but is apparently not connected with a metacarpal bone. He has nine children: 1st, a boy, has six fingers on each hand; 2d and 3d, normal; 4th and 5th, girls, each six fingers on each hand; remaining children normal. He knows nothing of his parents.

Dr. Wharton Sinkler had had a patient under observation some years before, who had a perfectly formed and useful supernumerary third finger, which was, he thought, connected with a supernumerary metacarpal bone. He was one of four sons, three of whom had supernumerary fingers or toes, as also had his father and some of his paternal uncles. There were no deformed females in the family.

Dr. James Tyson recalled two instances of this anomaly, the first in a colored boy, whose father presented the same condition; the second in an idiot, with no family history of heredity.

Dr. de Schweinitz mentioned a case in which this anomaly had passed through two generations. He also referred to a fœtus whose cystic degenerated kidneys he had presented to the Society, in which were present on each side six fingers and toes, in which dissection showed the supernumerary digits to be supplied with supernumerary metacarpal or tarsal bones.

The president had seen several cases of this anomaly in which the supernumerary digit was a mere dermal appendage, situated at the outer side of the hand near the base of the little finger. Two of these instances had occurred in the same family.

Dr. B. A. Randall asked if supernumerary metacarpal or tarsal bones are often to be found in these cases—a point rather neglected in the previous discussion.

Dr. Wharton had seen a case in which there was a well-marked supernumerary metacarpal bone, in connection with a perfectly developed supernumerary finger between the middle and ring fingers.

Dr. H. F. Formad had seen a case in which there was no corresponding metacarpal bone, while in one child's grandfather there was a well developed supernumerary metacarpal bone. The intervening generation was normal.

Dr. W. E. Hughes said that these, like all other anomalies, were very frequently hereditary, and, again, like other anomalies, were much more common in the colored race. There were all varieties of them, from mere dermal appendages, such as are present in the case to-night, to perfect fingers attached to perfect supernumerary metacarpal bones. Between these were cases in which a perfect supernumerary finger was attached to a normal metacarpal bone by a joint separate from the joint of the normal finger. Very rarely there were supernumerary carpal or tarsal bones.

Dr. Hare said the metacarpal or tarsal bones were rare, that dermal appendages

were quite common, and that bifid members occupied an intermediate position.

Dr. A. S. Roberts read notes on a case of deformity of the forearm and hand, with an unusual history of hereditary congenital deformity.

Dr. F. X. Dercum presented the brain of an epileptic imbecile. The dura was somewhat thickened, but not adherent. On puncturing it five ounces of cerebro-spinal fluid escaped. The pia was adherent in a few places. The ependyma was reddened and injected and the velum interpositum thickened. The convolutions were for the most part small and the sulci shallow. The frontal convolutions were little more than outlined and on the right the island of Reil was freely exposed. On each side the fissure of Rolando ran directly into the Sylvian. In the occipital lobes were the points of greatest interest. These lobes were remarkable for the smoothness of their surface. On the lateral surface only a shallow groove corresponded with the normal longitudinal occipital fissure. On the mesial surface the calcarine fissure was short and extended directly into the hippocampal, the posterior end bifurcated on the right, simple on the left. In the right hemisphere the parieto-occipital curved forward and ran for a short distance parrallel with the fissure of the corpus callosum, then abruptly turned upward, terminating upon the lateral surface. A comparatively well marked *pli de passage* was present, but made an obtuse angle or 120° with the calcarine. On the left the parietal-occipital made a right angle with the calcarine, and ran perpendicularly upward to end in a bifurcation on the lateral surface. On this side a large superior *pli de passage* was found. Microscopic examination of the paracental lobule showed the cells in the upper part of the cortex, though numerous, rounded or irregular; in the lower part the cells were comparatively few, pyramidal cells were the exception, and only one or two of the usual large cells were found. The walls of the vessels showed decided change. The reporter remarked that the brain could only suggest atavism in a remote degree, being essentially an arrest of development, which was most marked in the frontal and occipital regions. Further, the condition of the pia and the lateral ventricles, with the excess of cerebro-spinal fluid, point to a brain essentially diseased.

Dr. Formad presented the brain of an imbecile. As a young child the patient had been normal, the imbecility coming on after a sunstroke. The brain was markedly asymmetrical, the left cerebrum twice as large as the right, with an entire difference in the distribution of the convolutions. On the contrary the right lobe of the cerebellum was twice the size of the left. The head was shaped to suit the brain. Dr. Dercum said that from the fact of the brain fitting so well into the skull it would seem as though the condition might have been congenital. Still, in view of the traumatism and the age at which the symptoms commenced, he thought the condition rather one of atrophy. Not only were the primary convolutions perfect, but also the secondary; if it had been congenital the secondary convolutions would most likely be absent and the primary poorly formed.

Also an anomalous brain from a boy, æt. 9 years. He had been healthy and of fully average ability. Death resulted from an accident. There is an entire absence of falx cerebri, the two hemispheres being connected by a bridge of brain substance. There is nothing else abnormal.

Dr. Formad then continued his remarks on the characteristic lesions of chronic alcoholism, presenting illustrative specimens.

Dr. J. P. Stritmarter presented a primary sarcoma of the kidney, occurring in a child 5 years old. There was absence of a history of heredity. Enlargement of the abdomen was noticed soon after a fall and progressed rapidly. The tumor, hard, rounded, and painless, extended from the crest of the ilium to the margin of the ribs on the left, with nodules extending to the median line. Toward the end the lower extremities became œdematous and the superficial abdominal veins enlarged. She died 4 months after the first symptoms. Post-mortem, the left kidney was found enlarged to the size of a fœtal head, with a complete destruction of any normal structure. There were secondary deposits in the peritoneum, omentum, liver, spleen, and right lung. Dr. Formad said he had examined the growth and found it to be a congenital rhabdo-myoma, which had undergone sarcomatous change. Primary renal sarcomata rarely gives metastasis, and he accounted for the numerous secondary growths in this case by the fact that the sarcomatous change was secondary to the rhabdo-myoma.

Dr. T. S. K. Morton presented specimens from a case of pneumonia with meningitis. The patient, when first seen, five days after the initial symptoms, was profoundly comatose and rigid, with finely-contracted pupils and the physical signs of pneumonia. She died in a few hours with no change in the symptoms. The dura was in spots slightly

adherent. Extending the whole length of the longitudinal sinus was a firm white clot. A small vein, occluded by the clot, had ruptured and poured out about a drachm of blood. There was extensive suppurative lepto-meningitis, with considerable effusion in the ventricles. The upper lobe of the right lung was in a state of advanced red hepatization.

Dr. J. H. Musser said the extreme interest of this case arises from the association of apex pneumonia with meningitis, without any lesion in the body, as ulcerative endocarditis, or any septic process to account for their concurrence. As is well known in apex pneumonia, cerebral symptoms are very prominent; and being attributed to functional disturbance of the brain at the present day, there is no attention paid to the active treatment of them. This case teaches the valuable lesson that we must learn to treat these symptoms more actively in many cases, or we may expect frequently disastrous results.

Dr. Tyson said that notwithstanding the absence in the history of any traumatism he could not but think there might have been a blow on the head which was responsible for the pneumonia.

The President remarked the absence of any history of traumatism in the case by which the meningitis might have been caused, and brought into prominence the lesions of chronic alcoholism, a condition in itself strongly predisposing to meningitis. The cerebral symptoms appear to have been not only more intense, but also different in kind from those met with in pneumonia, and particularly apex pneumonia. Though, perhaps, not more intense than is sometimes seen in the apex pneumonias of children, they were certainly different in character. The association of the two diseases, pneumonia and meningitis, he thought accidental rather than causal.

Dr. C. M. Wilson presented a meningocele taken from a patient dying 16 days after birth. The brothers and sisters were healthy, but the youngest had in the temporal region a nævus. The child died in convulsions. The tumor which grew from the posterior fontanelle was as large as an English walnut, was filled with cheesy matter, and its cavity could be reached from the interior of the cranium.

The committee on morbid growths reported, 1, Dr. Dunn's specimen removed from the lumbar region of a cow shows a combination of mycoma with lipoma. 2. Dr. Roberts' tumor removed from the theca of the extensor tendon of the middle finger shows the structure of a pure fibroma.

Card specimens: Dr. W. A. Edwards, Head and Neck of a Tænia Solium. Dr. Morton, Bony Tumor projecting from right side of Falx Cerebri. Dr. J. M. Keating, Congenital Cystic Liver. Dr. R. G. Curtain, Tricuspid Insufficiency. Dr. J. S. Neff, Chronic Endo-Pericarditis, Heart weighing 56 oz. Dr. Tyson, Acute Pericarditis. Dr. Formad, Acute Pericarditis; Heart with three ventricles; Rhabdo-myoma of kidney; two cases of Spina Bifida; Congenital Diaphragmatic Hernia; Congenital Occlusion of Rectum.

Editorial Department.

Periscope.

The Philosophy of Drinking Largely.

We take the following from the *Lancet*, November 28:

We do not speak of drunkenness, albeit the poet has taught us *in vino veritas*. What we have now to say relates to the wisdom and reason of drinking largely of fluids which are in the first place and principally solvents and diluents. Not very long ago those unhappy folk who go wearily and sadly, because, forsooth, they are waxing fat, were warned to leave off drinking largely and to minimize the quantity of liquid they consumed. Never before, perhaps, was there a more mischievous "fad" imposed on a too credulous public than this reduction of the amount of fluid taken. Now the obese are, by the rotary madness of the crazy in physic, counselled to drink deeply. This, at least, is a safe policy, and whether or not it does anything in aid of the removal of fat, it will certainly not produce the evil consequences which have in too many cases been brought about by the abstinence from solvents and diluents. Our concern is not with the "anti-fat" movement; with this we have no sort of sympathy, except in so far as an accumulation of adipose tissue may chance to be morbid. Meanwhile there are physiological

facts in relation to drinking which ought to be recalled by those who know them, and brought to the knowledge of the unskilled in medicine, because they concern the promotion of health. Thus it is essential that there should be constantly passing through the organism a flushing, as it were, of fluid, to hold in solution and wash away the products of disassimilation and waste. Those who do not recognize the fact that three-quarters by weight of the entire organism is normally composed of fluid, cannot fully realize the great need which exists for a copious supply. If there be not a sufficient endosmose, the exosmose must be restricted, and effete matters, soluble in themselves, but not dissolved because of the deficiency of fluid available, will be retained. Take, for example, the uric acid; this excrementitious product requires not less than some eight thousand times its bulk of water at the temperature of the blood to hold it in solution; and if it be not dissolved it rapidly crystallizes, with more or less disastrous consequences, as in gout, gravel, and probably many other less well-recognized troubles. We only mention this particular excrement by way of illustration.

In all, it may be fairly concluded that not less than three and a half pints should be consumed by any person in the twenty-four hours, and when the body is bulky four or even five pints should be the average. It is, moreover, desirable that the fluid thus taken should be in the main either pure water or water in which the simplest extracts are held in solution. When fluid taken "as drink" is itself heavily charged with solid matter, it cannot fairly be expected to so entirely rid itself of this burden in the process of digestion and absorption as to be available for solvent purposes generally, although the separation between solid and fluid ingredients of the food is doubtless fairly complete in the processes preparatory to assimilation. The aim should, nevertheless, be to supply the organic needs in this particular abundantly, and with such fluids as are not overloaded with solids, but simple and readily available as solvents. Another urgent reason for drinking freely of bland fluids is to be found in the need of diluents. This is something slightly different from mere solution. Many of the solids of the tissue waste are of a nature to irritate and even disorganize the kidney, if they be brought to that organ for excretion in too concentrated form. There is no reason to suppose that the kidneys are liable to suffer from overwork if the specific excreting power of the kidney-cells be not too heavily taxed. If only the products of disassimilation be diluted, so that they can be passed through the kidney by the simple process of exosmosis, the organ will discharge its function without injury or exhaustion. As a matter of fact and experience, those who drink innocuous and unstimulating fluids freely do not suffer from kidney trouble, but are almost uniformly healthy, at least so far as the excreting functions are concerned. It is a popular fallacy that the kidneys may and ought to be relieved by the determination of fluid to the surface of the body and perspiration. Except in cases of organic disease of the kidney, or where, as in the elimination of a special product, it is desirable to use the skin as an emunctory, the fluid diverted from the kidney is wasted so far as flushing purposes are concerned.

Case of Diphtheria Complicating Syphilis.

Dr. Valentine Matthews thus writes in the *Lancet*, December 12, 1885:

The occurrence of diphtheria in a case of syphilis before secondary symptoms have appeared seems to me to be worthy of record. In the instance adduced it is obvious that, as the sore throat occurred about eight weeks after the first appearance of the chancre, the symptoms might easily, at the time of their occurrence, have been attributed to the secondary sore throat of syphilis. The aspect of the throat, as will be seen, was characteristic of diphtheria, and presented none of the appearances seen in a syphilitic sore throat. There could be no doubt, from its appearance, the absence of ordinary secondary syphilitic symptoms, and the subsequent palsy of the palate and paresis of the lower extremities, as to its diphtheritic nature. A point of interest in the case is the occurrence of salivation simultaneously with the diphtheritic symptoms. I have been unable to find any reference to diphtheria complicating syphilis; the only recorded case that I know of bearing at all on the subject is one in the *Medical Examiner*, 1876, by Dr. Macneill Whistler, which is, however, the converse of the present one.

F. D., aged twenty, a young man of somewhat irregular habits, who states that he had rheumatic fever in 1881, typhoid fever in 1882, and gonorrhœa eight months ago, came under observation on August 28, 1884, suffering from a Hunterian chancre on the corona of the glans penis, which he first noticed three weeks ago. With the exception of slight enlargement of the inguinal glands, there were no other symptoms of any kind.

He was placed under ordinary anti-syphilitic treatment, and progressed quite favorably, the sore being completely healed on September 19. He was seen on the 6th of the following October, when he had no symptoms of any kind whatever; but on October 9 he came complaining that he had had for the last two days attacks of shivering, loss of appetite, thirst, and sore-throat, with difficulty of swallowing. On examination, the tonsils and uvula were seen to be reddened, swollen, and covered with patches of whitish membrane. These membranous patches had a definite margin, and affected the left side chiefly. Temperature 101°; pulse 128. The anti-syphilitic treatment was immediately discontinued, and the patient ordered to remain in bed and have the fauces sprayed with the solution of sulphurous acid (B.P.) every three or four hours. By the next day (October 10) the greater part of the membrane had become detached and coughed up, leaving ulcerated surfaces behind, but the patient was profusely salivated. The gums and tongue became tender, œdematous, and swollen, and an ulcer about the size of a shilling began to form. The temperature remained between 100° and 102° for two or three days, and then fell to 99°, and shortly afterwards to the normal. To combat the salivation, precipitated sulphur was exhibited. The patient then made a steady recovery, and was advised to go away on October 29.

November 18, 1884. The patient went to Brighton for a fortnight, and on his return complained of difficulty of swallowing, that fluids returned through his nose, and that he had a nasal twang in his voice. This latter was extremely apparent. These symptoms, he stated, first commenced after he had been away a few days. On examination, it was found that the soft palate and uvula were drawn markedly to the right. The larynx showed no abnormal appearance.

By December 4, the voice and deglutition were much improved. The palate acted better, but the patient complained of fatigue in walking, and especially of weakness in the calves. He walked with great difficulty, even with the aid of a stick. On the 19th, the weakness of the calves continued, but the voice and deglutition were practically well. A papular syphilitic eruption had appeared on the trunk and arms, and the anti-syphilitic treatment was resumed. By January 3, 1885, the weakness of the calves had much decreased, and by the 26th the strength of the legs was entirely recovered. With regard to the syphilitic symptoms, the rash on the trunk and arms gradually faded, but on February 13 the patient suffered from ulceration at the angles of the mouth and alæ nasi, accompanied by a papular rash on the face. The symptoms, however, improved under treatment, and by April 13 there was no objective symptom, nor did any occur subsequently, although the patient remained under observation for some months longer.

On the Difficulties in Diagnosis in Ulcer of the Stomach.

Before the Medical Society of London, a paper was read on this subject by Dr. Stephen Mackenzie, who said that, while the diagnosis of ulcer of the stomach was common enough, occasions of testing its correctness were comparatively rare. It had to be borne in mind that cases presented themselves where an ulcer did exist, without giving rise to any particular or characteristic symptoms; and, on the other hand, there might be a complete clinical picture of gastric ulcer, without any such ulcer being discoverable at the necropsy. Dr. Mackenzie read the history of various cases exemplifying the uncertainty of the commonest symptoms, and the errors to which they might give and had given rise. Patients suffering from apepsia nervosa might conduct themselves in every respect like one suffering from genuine gastric ulcer. This condition was one, he said, characterized by absolute incapacity of the stomach to retain and digest food due to nervous causes. The author insisted on the fact that, in cases of nervous origin, any kind of food would probably be alleged to cause pain, even milk; and this, he said, was not generally the case in true gastric ulcer.

The president said that, after Dr. Mackenzie's paper, he was inclined to think that cases of apepsia nervosa were pretty common. He asked whether the craving for peculiar aliments, often of an eccentric kind, such as Dr. Mackenzie had mentioned in one of his cases, had any diagnostic importance. Dr. Ord said he had been struck by the disproportion which so often existed between the lesions and the symptoms to which they gave rise; extensive lesions sometimes causing but slight symptoms, and at other times insignificant lesions would set up quite a grave train of symptoms.

Dr. C. H. F. Routh said that the temperature of the food afforded a valuable diagnostic sign; that in gastritis and ulceration cold drinks were soothing, whereas in nervous cases only warm drinks had that effect. He thought, too, that the increased tenderness

over the site of an ulcer, on passing an electrical current, might be turned to account.

Dr. Samson mentioned the case of a medical man where an ulcer of the stomach which caused death was diagnosed as commencing pleurisy, owing to the absence of definite symptoms pointing to the stomach as the organ affected.

Mr. James Black and Dr. W. H. White quoted cases bearing out Dr. Mackenzie's views.

Dr. Theodore Williams insisted on the very localized tenderness in gastric ulcer.

Dr. Angel Money suggested that the condition of apepsia nervosa should be regarded as the disease present in all cases, and that the ulcer should be considered accidental. The diversity of results would thus be explained.

Dr. T. Stretch Dowse thought inquiries should be made with the view of ascertaining whether there existed any connection between cases of gastric ulcer and ataxia.

Dr. Fowler said that many cases diagnosed as gastric ulcer were attributable to organic disease of the heart.

Dr. Mackenzie, in reply, said that no symptoms could be regarded as pathognomonic. He did not think that gastric ulcers had any connection with ataxia, nor could he admit the probability of Dr. Angel Money's ingenious suggestion.

Right- and Left-Handedness.

Dr. Chudleigh thus writes in the *Brit. Med. Jour.*, December 12:

The functional asymmetry which makes one hand stronger than the other must have some anatomical basis which ought to be be discoverable; but no one yet seems to have detected the cause. Many a time have I gone over the unilateral structures of the body, to consider if any one of them was calculated to influence its own side for good or evil; but I was always accompanied in my search by this baffling forethought, that if I did succeed in finding some cause for a general excess of muscular nutrition in the right limbs, there would be a corresponding excess of nervous nutrition in the right side of the brain; an advantage which, by the the decussation of fibres, would be transferred to the left side of the body, and things would be equal again. Yet, in spite of this difficulty, I have been continually haunted by the idea that it is in the innominate artery, if anywhere, that we are to find the solution of the mystery. The innominate secures for its own subclavian and carotid these advantages over the subclavian and carotid which arise direct from the aorta on the other side. A tube of a given calibre is more effective than two tubes of half that calibre; therefore the innominate, besides serving as a kind of funnel-mouth to catch the stream, is a more effective channel than the subclavian and carotid together would be if arising from the aorta as two distinct tubes.

Again, the innominate lies rather more in a direct line with the aorta than do the two equivalent vessels on the other side; wherefore the innominate would have the advantage of lying more directly in the set of the stream. And the advantage of being a little nearer the heart, even if infinitesimal, is on the same side. Thus the "bend sinister" of the aorta, and the existence of the innominate artery, tend to increase the blood-supply of the arm and brain on the right side. This fairly accounts for a slight excess of muscular nutrition in the right arm; and a slight excess, by provoking use, would induce further development. But the right carotid has the same advantage as the subclavian; how is it, then, that equilibrium is not restored by an excess of nerve-force being sent across to the left of the body from the right of the brain? When we observe that ponderous muscular power can co-exist with a comparatively small brain, as in the elephant and boa, whereas a large brain with small muscle by no means implies muscular power, it seems fair to conclude that an increase of muscle produces more physical effect than an equal increase of nerve-matter, and that consequently the advantages of the innominate tell more on the muscle of the right arm than on the nerves of the left side of the body. But this only accounts for the superiority of the right arm; what can be said about the remainder of the right side? In the first place, not all the right side is superior to the left; next to the arm, it is mainly in the leg that "dexterity" is discernible. In the next place, the superiority of the right leg is not nearly so marked as that of the right arm, and may be due to the fact that a sense of power in the right arm inspires a sense of confidence in all else that is right, whence results more frequent use, and consequent development. Also the advance of the right arm often necessitates the advance of the right foot, as in sword-exercise. But in numerous other cases the left leg, if left to itself, displays a degree of forwardness which excites a suspicion that its inequality is not natural, but induced. I have asked a considerable number of the London Shoe-

brigade which foot their customers usually present first, and the replies have been that the left is first presented almost invariably.

The foregoing theory can be easily tested in several ways. Abnormal cases are occasionally noted where there is no innominate artery, the right subclavian and carotid arising directly from the aorta, like their fellows on the other side. I think that one or more such irregularities were observed last year in the dissecting-room of University College, Liverpool. It would be interesting to learn if there were a history of left-handedness in any of those subjects. Also it sometimes happens that the normal position of viscera is reversed, and all the organs are found to have changed sides. One such case is preserved in the College of Surgeons, and within the last few months another was reported from America. Is it possible to ascertain if left-handedness was observed in either of these?

Some of the facts connected with right and left are curious and interesting. If one offer the right hand to an European adult, the propensity to extend the right hand in return is so strong as to be almost a reflex action. A Bokhara sheik, who suspected Wolff of being a Frank, applied the test of offering him his hand; fortunately for himself, Wolff did not grasp the hand, but responded with a salaam in correct Oriental fashion. But in children, this propensity is either not yet developed, or else is overcome by an innate law of least action. I have tried the experiment of offering my right hand to scores of little children; they invariably give the left, which is nearest, and do not cross the right hand over. If I offer my left, they return the right, again swayed by a law of least action. In sliding on ice, my schoolfellows used to put the right foot forward almost invariably. Though the word Benjamin means Son of a Right Hand, yet the tribe seems to have been notoriously left-handed. The name may have been euphemistic, like Euonumos and Aristera. Von Miklucho Maclay says that Papuans are always left-handed. I should very much like to know something about the Papuan innominate.

Bacteriology of Certain Eye Diseases.

A Swedish physician, Dr. Johann Widmark, who has been engaged in the study of the bacteriology of some ophthalmic diseases, has isolated and propagated in cultures four different bacteria. These he brought into contact with the corneæ of rabbits, producing with each of the different species keratitis with hypopion, which, however, differed in its results from the disease occurring in the human subject as a complication of catarrhal inflammation of the lachrymal sac, as it never led to total destruction of the cornea, but merely left opacities of a greater or less extent. The writer offers a few ingenious suggestions on the etiology of some of the ophthalmic diseases which he has been studying. When the lachrymal canals act normally a continuous current of the secretion is kept up, which carries with it the microbes which have entered the sac; but if any obstruction exist, such as a stricture of the lachrymal canal, the contents of the sac become stagnant, and the microbes which are present there find conditions favorable to their development; they thus cause alterations in the contents of the sac, and this abnormal secretion exerts a violent irritation on the walls and produces an active migration of lymphatic corpuscles; thus the micrococci do not really produce the original affection, but they contribute to set up irritation and to increase the gravity of the disease. Keratitis with hypopion may be produced by several kinds of microbes. The different degrees of the affection are probably due to the different degrees of virulence possessed by the various microbes. The small abscesses of the ciliary roots in inflammation of the Meibomian glands are generally caused by the immigration of the two bacteria named Staphylococcus aureus and Staphylococcus albus. When these abscesses follow inflammation of the lachrymal sac, they are due to the growth of the microbes in the sac, and their subsequent passage with the secretion as it flows back into the conjunctival sac, carrying them to the ciliary roots. Phlegmonous inflammation of the lachrymal sac is usually due to a migration of Streptococcus pyogenes into the anterior subcutaneous tissue. Of the three pyogenic bacteria, two usually make their way to the ciliary roots, the third to the subcutaneous tissue round the lachrymal sac, and this appears to correspond exactly with the clinical manifestations: abscesses in the ciliary roots being generally strictly limited in extent, and producing but little effect on the surrounding tissue; phlegmonous dacryocystitis, on the other hand, frequently becoming erysipelatous. So, according to Ogston and Rosenbach, Staphylococcus albus and Staphylococcus aureus induce circumscribed abscesses, while Staphylococcus pyogenes gives rise to those of a more erysipelatous character.

Cases of Albuminuria Treated Successfully by Fuchsine.

Dr. A. T. Barnard thus writes in the *Brit. Med. Jour.*, December 5:

William R., aged 49, a collier, was admitted on May 8. He had never suffered from any previous illness, and said that he had been a moderate drinker.

There was extreme anasarca of the head, face, and legs, and ascites; the tongue was coated, the breath very foul, and the skin hot and dry. On inquiry, he said he had been working for some time in water in the pit. He complained of pain in the lumbar region. The urine, on examination, was of a pale straw color, and acid reaction, of specific gravity 1015; there was a slight deposit, and it became almost solid with albumen on boiling; under the microscope, granular casts were found. The quantity of urine passed was three or four ounces on the day after admission. The following treatment was adopted: a vapor bath was to be taken three times a week, and a drachm of compound jalap powder every second morning. He was ordered:

℞.	Tinct. digitalis,	♏x.
	Tinct. ferri perchloridi,	♏x.
	Aq. chloroformi ad,	℥j.

To be taken three times a day.

His diet was ordered to consist solely of skimmed milk, eight pints daily.

This treatment was continued until July 16, with the exception that the jalap powder was discontinued on July 15. During this period, the ascites and anasarca diminished, the amount of urine passed daily varied between sixty and seventy ounces, the amount of albumen also varied between one-half and one-third.

As he did not seem to improve under this treatment, a grain of fuchsine (in the form of pill, made up with compound tragacanth powder and extract of gentian,) was prescribed to be taken three times a day, and he was allowed ordinary diet.

On July 20, the dose of the drug was increased to two grains three times a day. The amount of albumen when the fuchsine was commenced being one-third, the urine containing crystals of uric acid and waxy casts. The urine (owing to the drug) now assumed a pinkish-red color, and the fæces were also colored.

In ten days the albumen was reduced to one-sixth, and on August 13 there was a mere trace, which continued until he was discharged (at his own wish), and made an out-patient, still continuing the fuchsine, which was now reduced to three grains in the day.

His urine was examined every week or ten days, and on the last three occasions there was a total absence of albumen, and nothing microscopically, the fuchsine being reduced to one grain in the day,

On September 30, the patient was discharged, and intended to recommence work.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. W. H. Atkinson, of New York city, has lately read several short papers of general interest before the Dental Society of New York, reprints of which may be obtained. One is on the General Definition of Disease; the other on Sponge Grafting as a means of reproducing tissue. He traces disease in general to a disturbance of the nutrient processes.

——The value of the Friedrichshall aperient mineral water in a wide range of diseased conditions associated with torpidity of the intestinal tract is well set forth by the testimony of a number of British, continental, and American physicians, published in a pamphlet, which may be obtained by addressing Fred. De Bary & Co., New York city. We have ourselves recommended the Friedrichshall in many cases for a number of years past, and its results have been such that we are persuaded that it is second to no aperient water to be found in the market. The water as now furnished is stronger than formerly, as it is obtained without admixture with the adjacent springs of ordinary water.

——In a reprint before us, Dr. Dudley S. Reynolds, of Louisville, discusses several of the causes of failure in operations for the correction of squint. The importance of this subject will be appreciated by all ophthalmologists, and Dr. Reynolds makes some valuable suggestions.

BOOK NOTICES.

Transactions of the Academy of Medicine in Ireland. Vol. III. Edited by Wm. Thomson, M. A., etc. Dublin: Fannin & Co., 1885.

This well-printed volume of nearly 500 pages contains a large variety of interesting

contributions to the different branches of medical science. Many of them are illustrated by maps and drawings, and by comparative tables. A careful article on cholera, by Surgeon-major Hamilton, seems especially appropriate in view of the late news of its continued prevalence in Southern Europe. The issues of such learned societies as the Academy of Medicine in Ireland should find a place in all our larger medical libraries.

A Compend of the Practice of Medicine. By Daniel E. Hughes, M. D. Physicians' edition, 8vo., morocco. Pp. 399. Philadelphia, P. Blakiston, Son & Co., 1886.

The object which the author of this book had in view was to prepare a convenient summary of the science of medicine, not unlike the quiz books used by students, but pitched on a higher note, and adapted to the use of physicians who wish to keep their memory fresh on those points which are apt to be studied for examinations, and promptly forgotten when these ordeals are passed. This is a good idea, and the author has succeeded very well in his scheme. He presents just enough to keep one well reminded of facts once acquired, without loading the mind with too heavy a task of new acquisition. It would be a right good thing for a physician to read this book over every year, just as Alexander Hamilton made it a rule to read over every year all the propositions of Euclid, in order that the fundamental principles of science may always be present to the memory.

Manuel de Technique des Autopsies. Par Bourneville et Bricon. A. Delahaye. Paris, 1885.

This is a well-written manual, neatly illustrated, and setting forth the most approved plans of making post-mortem examinations.

The Principles and Practice of Medicine. By the late Charles Hilton Fagge, M. D., F. R. C. P., etc. In two vols. Vol. I., 8 vo., pp. 1040. Phila., P. Blakiston, Son & Co. 1886.

Dr. Fagge, a London physician of a family long conspicuous in the profession, was a singularly energetic worker and an easy and pleasant writer. In the latter capacity he contributed numerous articles to the leading journals of Great Britain, translated Hebra's work on diseases of the skin, and prepared for the press the large and comprehensive treatise on the practice of medicine, the title of which is given above.

The last mentioned may be considered the crowning labor of his life, of a life unusually gifted, devoted to medical studies, and furnished with the results of that wide experience which only one of the great cities of the world can supply. To this undertaking, the magnitude of which he fully appreciated, he devoted more than twelve years of his time, but unfortunately did not live to witness its publication. The MS. was edited by Dr. Pye-Smith, a competent person, and now appears for the first time for the American market.

The first volume, the only one which has yet been issued, embraces the sections on general morbid processes, which include contagion, fever, inflammation, tubercle, tumors and syphilis; specific diseases; diseases of the nervous system; neuroses; and diseases of the respiratory system. Each disease is treated in considerable detail, and the facts are presented in a readable style. Every page gives evidence not merely of wide reading and close observation but of what is more rare than either of these, the power of reasoning accurately and presenting a subject lucidly. We cannot doubt but that this masterly production will meet with a ready reception from the American profession.

Wood's Pocket Manuals.

Cutaneous Memoranda. By Henry G. Piffard, M. D. Third edition.

Venereal Memoranda. By P. A. Morrow, M. D. William Wood & Co., New York.

The object of these little works is to supply the essentials of their topics in the smallest space possible and in the handiest form. This object is well attained in the specimens before us, which can be recommended as from the pens of competent writers and published in an attractive and eminently convenient form.

Wood's Library of Standard Medical Authors:

Climatology and Mineral Waters of the United States. By A. N. Bell, M. D., etc.

Diagnosis of Diseases of the Brain and Spinal Cord. By W. E. Gowers, M. D.

Diseases of the Lungs of a Non-Tuberculous Nature. By Prof. Germain Sée. Translated by E. P. Hurd, M. D. New York, William Wood & Co.

The three volumes named above are the most recent additions to Wood's Library of Standard Medical Authors. They present a variety of topics, all interesting, treated by authorities of different nationalities—a French professor, an English physician, and an American sanitarian. The work of Dr. Bell will probably be the most generally attractive. It is a carefully-prepared treatise, and the author has enjoyed unusual opportunities.

THE

Medical and Surgical Reporter

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE INTERNATIONAL MEDICAL CONGRESS.

In answer to a query from a physician in Paris to to whether the International Medical Congress will be held in this country in 1887, the *Medical Record*, January 9, says:

"If we were to give to the foregoing inquiry an answer unreservedly in the affirmative, we should be misrepresenting matters to our Parisian confrères. It is announced positively and officially that there is to be an International Medical Congress. But we must add to this that the American profession is seriously divided over the matter of its management, and that a considerable part of the best men of the profession have been excluded, or have been forced in self-respect to withdraw from all connection with it.

"We are glad to state, however, upon authority, that efforts for a compromise are now being made, and that there are a number of prominent gentlemen in this city, who have heretofore held aloof from the Congress, who are willing to join hands with the present management if such concessions are made as will enable them to do this properly.

"We shall be able, probably within a fortnight, to say whether these hoped-for arrangements have been made, and we shall make the announcement to our French confrères at that time.

"If they are not made, and the present dissensions and disagreements continue, we cannot conscientiously advise foreign physicians to come over here."

While we regret to be compelled to do so, we can only characterize the above as a wilful and deliberate effort on the part of our contemporary to injure the Congress, because a few distinguished leaders in some of our eastern cities so desire.

We most emphatically say that "*a considerable part of the best men of the profession have*" NOT "*been excluded;*" those who are out in the cold, are there because they chose to be—they resigned the positions to which they had been appointed, solely because they found themselves unable to control the American Medical Association, and through it the Congress.

Rather than suffer themselves to be left out, they are willing to let the impression go abroad that the Congress is doomed to failure.

We are satisfied that these gentlemen resigned their positions under a misapprehension; it was supposed that the American Medical Association would be unable to withstand their defection, and would alter its whole course rather than do without them.

But it was forgotten that times had changed since Philadelphia, New York, and Boston ruled medical America; the fact was overlooked that we have a great West and a great South, and that while the whole medical world is ever ready to pay all due respect to the Eastern magnates, it is not as ready as it was to be controlled by them.

Away back in the twenties, when a few men sought to control the medical profession of England, after a while the rank and file revolted and the warfare waxed so high that on one occasion the elder Mr. Wakeley, the champion of the masses, was *forcibly* ejected from the theatre of the College of Physicians (of which he was a member in good standing) by order of the Council.

While we have not yet come to such a pass in this country, and it is to be hoped we never shall, yet the position is somewhat similar.

A few leaders are endeavoring to autocratically govern the mass of the profession, and, apparently, stand ready to endeavor to ruin that which they cannot rule.

In the meantime the regularly-authorized Committee of the American Medical Association are going steadily forward, making arrangements for the Congress that *will be held in Washington in* 1887.

This committee is the agent of the American Medical Association; and right here, we wish to say most emphatically and most clearly, *that we have no sympathy with nor support for any committee, or any set of men, as a committee or a set of men,* BUT WE DO MOST POSITIVELY ASSERT THAT EVERY TRUE PHYSICIAN UNQUESTIONABLY OWES HIS ALLEGIANCE TO THE AMERICAN MEDICAL ASSOCIATION, and is in honor bound to abide by, aid, and support its decisions.

The Congress is being organized under its auspices and direction, hence every man who believes in subserviency to law and order must give his support to this organization.

If the Association at any time sees fit to reconsider its action, if it modifies or changes in toto its present attitude, such change will receive our most cordial support, as it should that of every right-minded man.

Let it be but clearly understood that the question is not that of supporting one or the other party, but of supporting or rebelling against the power of the American Medical Association; let it be realized that, unfortunately, many of our leaders are on the side of opposition; let it be appreciated that their position is much like that of minority leaders in South American Republics, who would rather ruin than be governed by those who are distasteful to them; let these points be clearly understood, and the whole matter is plain.

There can be but two sides to this question. On the one hand are arrayed those who would support the American Medical Association; on the other, those who would crush it because it will not do their bidding.

Next spring will decide who are in the majority.

In the meantime let us again most positively state that the Congress will be held, and will be well worthy of attendance.

THE SCHOOL BOOK TEMPERANCE CRUSADE IN PENNSYLVANIA.

Two pamphlets are before us, one by Mrs. Jos. D. Weeks, "Superintendent of the Department of Scientific Temperance Instruction" of the Woman's Christian Temperance Union of Pennsylvania; the other the reprint of an editorial by Dr. Henry Leffmann, of this city, on "Temperance School Books."

Mrs. Weeks gives a report of her labors in securing the passage of the law in this State which forced upon the public schools the use of text-books of physiology and hygiene which teach that the use of alcohol in any form as a beverage is ever and always injurious.

This is what she and those of her army call "scientific" temperance instruction! The absurdity, the untruthfulness of such a claim is known to every unbiased physician, physiologist and historian. The object in these books is not to teach what is true, but what is agreeable to the sentiments of a class, and what is salable under the statute. It is the grossest perversion of the name of science which can be shown in the record of even the careless and corrupt legislation at Harrisburg.

Dr. Leffmann points this out in a few but strong words in his editorial. Himself an expert chemist and able physiologist, he feels how false is the position of those who try to substitute their own wishes for the truths of nature. He observes:

"There is no doubt that under the stimulation of the law, a large number of text-books of a highly strained and artificial character have been produced; that prominent book firms are now engaged in spending large sums of money for the purpose of bribing and corrupting those who have the control of the text-books in the schools; and further, that a strong effort is being made to secure the endorsement of particular books, not because they have scientific merit, per-

spicuity, or capabilities of instruction, but because they conform to an arbitrary standand largely sentimental; in fact, because they are 'orthodox' on the question."

The ultra temperance agitators flatter themselves that they have gained a great victory in this law for the promotion of lying. But false methods injure good causes, and this attempt to cram into school children what they will be sure to unlearn in after life, will surely hurt the cause of judicious temperance, the benefit of which is conceded by all, and which all are ready to advocate by *honest* means.

TECHNIC OF THERMOMETERS.

At the last meeting of the Academy of Sciences of Berlin, Prof. Auwers reported on a series of experiments which H. F. Wiebe, together with Prof. Abbe and Dr. Schott had been making in Jena, with regard to the technic of thermemeters.

All thermometers now in use are imperfect in so far that the glass tubes containing the mercury cannot resist the influence of warmth.

Wiebe has discovered a glass which can be easily prepared, and which is affected by heat in far less degree than the kinds of glass in use up to the present. The glass of Wiebe, which he calls the "Tenenser glass," on continued exposure to heat, at 100 degrees, shows a fault of only $\frac{1}{20}$ degree, which is of no importance. The "Tenensen" glass is composed of

67.5 parts Ac. silicicum,
14.0 " Natron,
7.0 " Zinc. oxydatum,
7.0 " Lime,
2.5 " Aluminium oxydat. ($Al_2 O_3$),
2.0 " Acid. boricum.

Another kind of glass, which has the same qualities, is composed of

52.0 parts Ac. silicicum,
9.0 " Potassium,
30.0 " Zinc. oxydat.,
9.0 " Ac. boric.

ANTISEPSIS IN THE GERMAN ARMY.

For some years past the military authorities of Germany have had in view the introduction of an antisepsis in the treatment of wounds on the battle-field. This method would hinder the wound from becoming a receptacle for microbes, and without claiming perfection for it, or asserting it to be the only correct treatment, still, as Dr. v. Bergmann said on the occasion of the 55th German "Naturforscher Versammlung," it almost reaches the ideal treatment of wounds. Last spring at the suggestion of the Empress, the Minister of War called a conference of prominent military physicians, surgeons, and hygienists, to decide as to the advisability of introducing antiseptic treatment on the battle-field and in the military hospitals. The question having been answered affirmatively, the military authorities have asked for the sum of 800,000 marks, which have been granted, for 1886–87.

Another question now arises, namely, whether the army has a sufficient and competent staff, who understand the application of antisepsis? According to the most prominent authorities, the successful application of this treatment requires a thorough scientific education, each separate case having to be carefully judged and considered, and the treatment fitted to the individual circumstances.

Notes and Comments.

The Relation of Phthisis and Pneumonia to Syphilis.

That there is a form of degeneration of the lung due to syphilis, as well as a consolidation due to the same cause there can be little doubt. Dr. William H. Porter (who contributes a very interesting article on the subject to the *N. Y. Med. Jour.*, August 1), defines pulmonary syphilis as a condition of the lungs in which there is a progressive thickening of the walls of the vesicles; this change is often associated with inflammatory deposits, gummy formations which, degenerated into cheesy masses, become encapsulated or liquefy, and give rise to cavities. The first is best classified as syphilitic pneumonia, the second as syphilitic phthisis.

He concludes his article as follows:

1. *Ætiology.*—Pulmonary lesions attributable to syphilis are very common, more so in females than in males with the maximum number of cases occurring between thirty and forty years of age; it is as frequently, if not more frequently, inherited than acquired.

2. *Pathology.*—Is most frequent at the apex; usually involves both lungs; is a peculiar pneumonic process in the early stages, while later cavities are formed, and it becomes phthisical in the sense of progressive consolidation, followed by softening and the formation of cavities. There is a strong resemblance, but a positive difference, between syphilitic and tubercular phthisis, and a

positive anatomical difference between a syphilitic and a military tubercle.

3. *Symptoms.*—These are peculiar and diagnostic.

4. *Diagnosis.*—This rests mainly upon the rational history and physical signs, the extreme dyspnœa, the periosteal tenderness, and an absence of an increased bodily temperature.

5. *Prognosis.*—This depends upon an early recognition of the trouble.

6. *Treatment.*—It must be anti-syphilitic to be of any avail. Many cases are unaffected by iodide of potassium alone, unless under enormous doses, but a rapid improvement follows upon the use of the biniodide of mercury, iodide of ammonium, and the iodide of potassium.

The Nature and Treatment of "Blackwater Fever.

The *London Med. Record*, July 15th, says: We are indebted to French naval surgeons for almost all we know of this particular form of fever, which they describe under various names—*e. g., Fièvre bilieuse melanurique, F. pernicieuse ictérique, F. bilieuse nephrorrhagique, F. icterodes remittens*, etc. English writers on the diseases of tropical climates are singularly silent on the subject. Dr. Farrell, acting colonial surgeon of the Gold Coast Colony, whose pamphlet is printed for the Government of the colony, gives a very good account of this fever, with cases and temperature charts. He strongly maintains its paludal or malarial origin. The peculiar clinical features of the fever are, that it only attacks those already deteriorated in health. It is very often preceded by simple attacks of intermittent fever, with progressive anæmia and sallowness. The onset is invariably sudden. The quality of the vomit and urine is peculiar. The jaundice is uniformly distributed, not in patches of varying degrees of intensity; it is seen from the very first onset of the disease, and varies with the general condition. The type of accompanying fever is remittent or intermittent, even in the worst cases. The appearance of the face is dejected; the conjunctiva is yellow, but not injected. There is tenderness of the gastro-hepatic region. The pulse follows the fever. It is not contagious. In all these respects it differs from yellow fever. The urine gives no reaction of bile; but, on the contrary, the spectrum of hæmoglobin. Microscopy shows a few altered blood-corpuscles, amorphous granules, a few epithelial casts, triple phosphates, and acid urates. Heat and nitric acid give a variable proportion of albumen. Sodium chloride and acetic acid show the characteristic crystals of hæmatin. The prognosis is necessarily grave. As regards treatment, the author recommends large doses of quinine, calomel at the onset, and occasionally afterwards, in doses of from ten to twenty grains, not only for its action on the liver and as a sedative to the stomach, but an antiseptic, which may serve to minimize the self-infection which is apt to occur in fevers of this kind.

The Hæmostatic Properties of Ambrosia Artemisiæfolia (Rag-weed).

Dr. J. H. Hill reports this case in the *North Carolina Med. Jour:*

"On the morning of the 12th of May, at 8:30 o'clock, I was called to see Ellen Dosmond, aged eight years. I got the following history from the mother: Had recently removed to Goldsborough from Norfolk, Va. For the past five years had been subject to frequent spells of epistaxis, for which she had been treated by four physicians of Norfolk, frequently requiring the plugging of the posterior nares. Any slight cut would bleed excessively, and they were afraid to have her teeth extracted, she bled so. Two years ago had her ears pierced for earrings, and the hemorrhage was so great they feared she would die. I found a stout girl, well grown for her age, but the complexion muddy, face puffed, no purpuric spots, though at times, her mother said, her face was covered with purple spots the size of a pin's point. She was bleeding freely from the left nostril. I gave her a portion of rag weed to chew, and had a strong infusion made, of which I gave her a tablespoonful every half hour. I made a plug of some of the weed and inserted it into the nostril; in fifteen minutes all bleeding had stopped. I called again at 10:30 o'clock—no bleeding; at 1 o'clock—no bleeding. At 6 o'clock the grandfather called to see me, and said the child was up and playing about, and has continued so ever since."

Sudden Origin of Diabetes.

I will now, said Dr. Pavy, before the last meeting of the *Brit. Med. Ass.*, refer to instances where the disease has come on suddenly. In December, 1876, I was consulted by a lady, aged 35, in whom diabetes had supervened quite suddenly, four weeks previously. She was, at the time of the attack, nursing a two-months'-old infant, when her

supply of milk ceased all at once; and, contemporaneously with the cessation of the lacteal secretion, she noticed that she became very thirsty, and passed an abnormal quantity of urine. Four years previously she had sustained a severe nervous shock, with injury to the spine, in a railway collision, which led to her being bed-ridden for a period of eight months. She was, however, supposed to have recovered perfectly from this accident, and I am, of course, quite unable to say whether it had any bearing on the production of her subsequent illness.

Another instance of the disease coming on suddenly, occurred in a lady, who dated her illness from one evening when she had dined out with friends. Previously to this, her her health had been in all respects good. In the course of the evening she became very thirsty, with a thirst that nothing could quench, and she was at once afterwards recognized to be suffering from diabetes. Here the history was very clear; nothing unusual had been remarked during the day, until in the evening the thirst manifested itself.

Yellow Oxide of Mercury in Dyspepsia Due to Chronic Hepatitis.

Dr. E. A. Frimont thus writes to the *Med. Age:*

I have a clinical case under treatment which induced me to try tablets of yellow oxide of mercury (P., D. & Co.'s), and as the result has been very satisfactory, I hasten to make a note of it for the benefit of the medical profession.

A lady, 35 years of age, called on me complaining of periodical pains about the epigastrium and a pronounced sensitiveness in the right hypochondrium, with errratic uneasiness in her shoulder. Symptoms of jaundice were well marked; tongue coated; temperature and pulse normal. On percussion I detected an enlargement of the liver, the encroachment of which on the thorax gave rise to irregular respiration and fatigue. Digestive troubles were present in the form of dyspepsia. I did not hesitate to make a diagnosis of chronic hepatitis, with dyspeptic complications.

It occurred to me to try the tablets of yellow oxide of mercury, and after fifteen days' use of them, I am gratified to learn that my patient complains neither of suffocation nor of gastric disorders, and now by a thorough palpation I discover that the hepatic enlargement has so diminished that the liver has almost regained its natural size.

Gonorrhœal Rheumatism.

Whether there is or is not, such a disease has been repeatedly discussed, strong arguments being advanced on either side. Dr. R. W. Stewart, who contributes a long article on the subject to the *Cincinnati Lancet and Clinic*, November 7, 1885, thus concludes:

To sum up, I believe the disease, gonorrhœal rheumatism, exists for the following reasons:

1. Because the gonococcus of Neisser has been demonstrated, not only in the urethral secretions, but also in the effusion about a joint.

2. That in the majority of cases reported, even by those opposed to the existence of the disease, the following array of symptoms has been presented: Little or no fever, affection limited principally to one, or, at most, to two joints; presence of hydrarthrosis or synovitis; pain and swelling.

3. That in numerous cases the rheumatism always recurs when gonorrhœa is present.

4. That cases of rheumatic affection, in which the presence of a gonorrhœa had not been suspected, were treated without avail, until the gonorrhœa was found and cured.

Optic Neuritis in Kharkoff.

From a paper by Dr. Schmidt, in the October number of the *Russian Ophthalmic News*, we learn that during the last thirteen years the number of patients with optic neuritis seen in Prof. Hirschman's ophthalmic clinic in Kharkoff has been 279, these cases forming four per cent. of the whole. The majority were male patients. Generally both eyes were affected, the disease being confined to one eye in 30 cases only. By far the largest proportion occurred in patients of from twenty to forty years of age. The ophthalmoscope showed that 180 were cases of papillitis, 82 of papillo-neuritis, and 17 of neuritis retrobulbaris. Most of them were due to syphilis, and were accompanied by internal syphilitic affections, kidney disease, emaciation, etc. The cause of the disease could not in many cases, however, be clearly made out. The result was usually more or less complete atrophy, the cases of improvement being less numerous, and those of cure least of all so.

The Insidious Onset of Diabetes.

In the *Brit. Med. Jour.*, December 5, Dr. F. W. Pavy thus writes:

Now, as to the mode of onset of the disease; in one set of cases this takes place

gradually and insidiously, in another, quite suddenly. I do not doubt that in many instances it may exist for some considerable length of time, without exciting any suspicion of its existence. I have occasionally been enabled to prove this in patients living in the country, especially in clergymen and persons who wear clothes of black cloth, through the white stains, which are left on drying, from the urine which has splashed over the trousers, while micturating against a wall or on the ground. Such stains are very troublesome to remove by brushing, and when found on trousers which may have been put aside and not worn for a few years, as sometimes happens, we are at liberty to assume that the urine at that time contained sugar. I have heard of hotel servants, whose duty it was to brush the clothes, recognizing diabetic patients from the difficulty experienced in brushing out these stains. I have noticed that it is especially in elderly people that we find this gradual onset.

Cases of Cure in Diabetes.

Dr. F. W. Pavy thus spoke before the last meeting of the Brit. Med. Ass.:

"Although diabetes, when once developed, generally persists, cases occur where it has disappeared. I have, from time to time, met with these cases in my practice; I do not allude to a mere control of the disease under dietetic management, but a complete eradication. For instance, in May, 1881, I saw a gentleman, aged 41, who was the subject of the disease, and was passing a large quantity of sugar in his urine, which had a specific gravity of 1036, and contained 57 per 1,000 of sugar. This patient was highly neurotic. My last recorded observation about him is dated March 13th, 1884, at which time the sugar had entirely disappeared from the urine, although the patient was not dieting himself in the least, and ate of anything that came before him. Curiously enough, his wife had become the subject of the disease. She consulted me on that account in January, 1884, and I rather apprehend that it will not disappear from her in the same manner that it has disappeared from her husband."

Acute Febrile Glycosuria.

The following rather unique case was related to the last meeting of the British Medical Association by Dr. E. M. Skerrill:

The special peculiarity of the case was the association of a febrile attack, possessing no specific features, with a condition of acute glycosuria, in which the characteristic symptoms of diabetes—thirst and the excretion of a large amount of sugar-laden urine—were prominent features. The fever persisted for eleven days, and during this period the diabetic phenomena were pronounced; and with the subsidence of the pyrexia, the sugar disappeared from the urine. As respects the exact relationship of the fever and the glycosuria in this case, inasmuch as there is no reason to believe that the excretion of sugar in itself has any tendency to excite pyrexia, this instance must be regarded as analogous to those cases of intermittent fever in which the glycosuria is directly induced by the febrile state, and where its phenomena disappear when the fever abates.

The Use of Tobacco.

The *Quarterly Journal of Inebriety* tells us that M. Vallin read a paper before the French Society of Hygiene on the danger from the use of tobacco. He showed that cardiac narcotism, manifested by an intermittent pulse and tendency to faint, was common among excessive users of tobacco. A discontinuance of its use would be followed by a cessation of these symptoms. In children, chloro-anæmia and diminished blood corpuscles were present. Blowing sounds were noted in the carotid arteries, and a general dullness was noticed. Young persons with this chloro-anæmia from the excess of tobacco often develop pulmonary phthisis. Women who smoke suffer more than men, and have more cardiac symptoms. Young men who use tobacco to excess, are more often inclined to find in alcohol a relief from their nerve disturbances, and hence more often resort to drink.

Anisic Acid as an Antipyretic.

From the *Therapeutic Gazette* we note that one of the most recent additions to the list of antipyretic remedies is anisic acid, formed by the oxidation of the oil of anise. It occurs in the form of colorless, prismatic crystals, soluble in alcohol and ether. In its antipyretic effects it resembles salicylic acid, and it is decidedly antiseptic. It causes increased arterial tension, and has a feeble toxic action, causing epileptiform convulsions in animals when it is injected into the veins in large quantities. In its pure state it is said to form a good dressing for open sores. Its use as an antiseptic is not followed by any unpleasant after-effects, as is sometimes the case with salicylate of sodium.

Acorn Chocolate for Diarrhœas.

The *National Druggist* tells us that in the Augusta Hospital for Children, in Berlin, diarrhœas, acute and chronic, are most successfully treated by giving the patients to drink almost *ad libitum* a kind of chocolate to which the name of *Eichel-cacao*, or acorn chocolate, has been given. It consists of cacao which has been freed from its oily principle, mixed with an aqueous extract of roasted acorns, with the addition of toasted cornmeal to give the fluid a consistency, the whole being sweetened to suit the taste. The drink is taken with avidity by the little patients. It tastes like chocolate, in fact, can scarcely be distinguished from the pure article, and is very nourishing. It has proven of exceeding value in the treatment of chronic diarrhœa especially.

Cocaine in Whooping-Cough.

Dr. Prior, of Bonn, (*Berliner klinische Wochenschrift*), has treated several cases of whooping-cough with cocaine, with good results. As is evident on *a priori* grounds, he does not consider the drug a specific, but simply a means of relieving and reducing the number of the paroxysms. He used fifteen and twenty per cent. solutions to paint the fauces, the inter-arytenoid fossa, and the vocal cords, with the result of prolonging the interval between the attacks, and lessening the severity of these. The treatment was resorted to twice daily, great stress being laid on the necessity of producing at the time complete anæsthesia of the fauces and upper part of the larynx. Inhalation of a twenty per cent. solution four times a day was not so successful as painting.

Diabetic Coma.

Acetonemia has, not infrequently, been set down as the cause of diabetic coma; but as with every other point in connection with this little understood disease (diabetes), this theory has had its opponents, and among them we must class Dr. F. W. Pavy, a distinguished authority on the disease, who told the last meeting of the British Medical Association that he is inclined to believe that the coma depends on an exhaustion of certain nerve centres. A simple attack of vomiting may lead to it in a diabetic patient, who has not been able to eat anything for a day or two. Fatigue, or anything which tends to throw the patient off his balance, will conduce to it, and he has often seen it in patients who have undertaken long journeys to see him. They were buoyed up by hope on the way, but when they presented themselves in his consulting room, he recognized the first indications of the advent of coma, and the patient has died in a day or two.

A Prostatic Catheter.

To the Clinical Society of Maryland, (*Maryland Med. Jour.*, October 31,) Dr. Christopher Johnston, Jr., showed a catheter made at the suggestion of Dr. Christopher Johnston, Sr. The instrument was peculiar in having a wedge-shaped point with lateral openings. The wedge assisted its passage through the prostate, while the lateral openings facilitated the drainage of the bladder. At the distal extremity this instrument was curved anteriorly for about $\frac{1}{3}$ its length, to an angle of about 45°, the curvature being claimed to assist the patient in introducing it himself while in the erect position.

Correspondence.

Rapid Dilatation of the Cervical Canal of the Womb for Sterility and Dysmenorrhœa.

Eds. Med. and Surgical Reporter:

So many of the readers of your valued Journal have written to me for a description of my mode of rapidly dilating the canal of the womb, for sterility and for painful menstruation, that I ask permission to reply to them through your columns.

The instruments which I employ are two Ellinger dilators of different sizes. These are the best, on account of the parallel action of their blades. The smaller of these dilators has slender blades, and it pilots the way for the other, which is much more powerful, and with blades that do not feather. I have had the beak of each dilator changed from the original obtuse angle to a slight curve, so that either can be reversed within the uterine cavity without twisting the womb on its axis. The lighter instrument needs only a ratchet in the handles, but the stronger one should have a screw with which to bring the handles together. Lest the beak should hit the fundus uteri and seriously injure it when the instrument is opened, the blades are made no longer than two inches, and are armed with a shoulder which prevents further penetration. The larger instrument opens to an outside width of one and a half inches, and it has a graduated arc in the handles by which the divergence

of the blades can be read off. The blades are roughened by shallow grooves, or corrugations, which keep the instrument from slipping out. These instruments have been made under my supervision by Messrs. J. H. Gemrig and Son, of Philadelphia, and I can recommend them highly.

In a case of dysmenorrhœa, or in one of sterility from flexion or from a narrow canal, my mode of performing the operation of rapid dilatation is as follows: The patient is thoroughly anæsthetized, and a suppository containing one grain of the aqueous extract of opium is slipped into the rectum. She is then placed on her back and drawn to the edge of the bed, the knees being supported by her nurse. The vagina is next thoroughly cleansed with a 5% solution of carbolic acid. By the aid of a strong uterine tenaculum, applied through my bivalve speculum, the cervix is steadied, and the smaller dilator is introduced as far as it will go. The light must be good, so that the operator may see clearly what he is about. Upon gently stretching open that portion of the canal which the beak occupies, the stricture above so yields that when the instrument is closed it can be made to pass up higher. Thus, by repetitions of this manœuvre, little by little, in a few minutes' time a cervical canal is tunnelled out, which before could not admit the finest probe. Should the os externum be a mere pin-hole, or be too small to admit the beak of the dilator, it is enlarged by the closed blades of a straight pair of scissors, which are introduced with a boring motion. As soon as the cavity of the womb is gained, the handles are brought together, and the canal kept dilated for about five minutes. The small dilator being now withdrawn, the larger one is introduced and the handles are slowly screwed toward one another.

If the flexion be very marked, this instrument, after being withdrawn, should be reintroduced with its curve reversed to that of the flexion, and the final dilatation then made. The ether is now withheld, and the dilator kept *in situ* until the patient begins to flinch, when the instrument is closed and removed, and the vagina again syringed out with the solution of carbolic acid. A few drops of blood trickle out of the os. Occasionally a slight flow of blood will last for several days after the operation, simulating the menstrual flux. Often this flux is precipitated or it is renewed, if the operation follows or precedes it too soon. The best time for dilatation is therefore midway between two monthly periods.

In the great majority of cases I dilate up to one and a quarter inches. Sometimes, in an infantile cervix, which does not readily yield, and might give way, the handles are not screwed closer than three-quarters of an inch or an inch. Slight tearing of the cervix has happened to me four times out of two hundred and twenty-three cases; but the rent was not large enough to need any stitches. For slight dilatation, such as for the office treatment of sterility or of dysmenorrhœa, or for the introduction of the curette, or of the applicator armed with medicated cotton, the more delicate instrument is quite strong enough, and an anæsthetic is not needed.

After the full dilatation under ether, the patient needs rarely more than two or three suppositories, and complains merely of soreness for one or two days. To forestall any tendency to metritis, she is kept in bed until all tenderness has disappeared. Pain is met by rectal suppositories of opium, and by large poultices laid over the abdomen. I have seen slight pelvic disturbance arise from this operation, but it has always been readily controlled, and has not given alarm.

Of what this operation can accomplish let me give one illustration. An unmarried lady had from puberty painful menstruation. This grew worse, as it usually does, until it became too severe to be controlled by chloral or even by hypodermic injections of morphia. Anæsthetics were finally resorted to, and her health began to break down under the strain. At one monthly period her agony was so great that two physicians were employed for forty-eight hours in taking turn about in keeping her under the influence of chloroform. This experience induced them to send her to my private infirmary, where the sharply anteflexed and narrow canal was dilated to the extent of one and a quarter inchs, in the manner which I have described above. This one operation so effectually cured her that she has not since needed to take to her bed or to resort to narcotics dur her monthly periods.

WILLIAM GOODELL, M. D.

Ether or Chloroform after Cocaine.

EDS. MED. AND SURG. REPORTER:

In your journal for December 26, 1885, page 748, an error occurs which should be corrected, and concerning which I write you as I am in part responsible for it. In the narration of the case in question, in which, after the hypodermic administration of cocaine, it became necessary to employ general narcosis (chloroform being selected as the

anæsthetic), I was fully impressed with the idea that death ensued, and so stated in the discussion at the Pathological Society. In order to ascertain the particulars of this case, I wrote to the surgeon who had spoken to me of it, and then learned that although the patient made a narrow escape, he was restored by artificial means. In the minutes of the Society at the next meeting I corrected this error.

I think this experience justifies the employment of great caution in attempting narcosis by ether or chloroform after cocaine. Chloroform is such a dangerous agent, that its use, already restricted to a limited number of cases by a large majority of leading American surgeons, should be certainly excluded from patients already under the influence of cocaine.

JOHN A. WYETH, M. D.
New York City.

NEWS AND MISCELLANY.

The Popularity of the Pennsylvania Hospital.

This is one of the very few institutions of the kind that have been started and kept up so long with little or no aid from the public fund. Except that the Provincial Assembly of Pennsylvania voted a small sum in 1751, and that the Assembly gave at the close of the last century about $70,000 for the erection of additional buildings, the hospital has had no aid from State or city government. It has lived and grown great upon the free gifts of the citizens of Philadelphia and Pennsylvania. Never was an institution started that carried with it at the outset such manifestations of popular favor. Mechanics, and even the poorest day-laborers, deducted something from their ordinary wages for the benefit of the hospital, and it is to the credit of the successive managers that they have never forgotten this early aid, and while there has been a bed or cot in the place, no sick or injured mechanic, nor no maimed or infirm member of a laborer's family has ever failed in the past one hundred and thirty years to find ready care and treatment at the Pennsylvanla Hospital. Holders of real estate sold to the hospital for less than they would have sold in an ordinary bargain ; contested sums of money and unclaimed sums in the hands of trustees were deposited with the hospital, the curious-minded paid an admission fee and there were charity boxes in different parts of the city into which the poor dropped their little mite. It was not through royal grant that this great public charity was started, not through the munificence of the rich proprietors, nor through the great contributions of the wealthy, but through the generous self-sacrifices, the labor and the small gifts of the poor. It sprang directly from the people as a popular institution, and has been supported by the people, and for the help of suffering humanity of whatever race, creed or condition, ever since.

Quinine in High Altitudes.

Dr. S. D. Bowker, of Kansas City, Mo., writes to the *Medical Record:*

"In a recent number of the *Med. Record*, Dr. Ralph M. Cole, of Idaho Springs, Col., in a report of a case in which quinine was used, says, 'it is necessary to observe great care in the use of this drug in high altitudes.' For the benefit of parties with a short experience in high altitudes I will say, that ten years in Colorado, four of which were spent in Central City, only four miles from Idaho Springs, taught me that Dr. Cole's conclusions will not do as a guide to practice. I went there in 1871 with a similar impression to his, without knowing just how I got the information. What was called 'mountain fever' was then raging, with a heavy death-rate, and I found to my regret that small doses of quinine would not meet the emergency. I was informed by Dr. L. C. Tolles, who has practiced in Central City nearly twenty-five years, that his first years there were spent under the false impression of Dr. Cole. He somehow got the notion that high altitudes contra-indicated the use of quinine, so that he almost discarded it, even in small doses. But, greatly to the benefit of his patients, he discovered that no climate in this country would tolerate, and even demand, as large doses as the high altitudes of Colorado. Ten grains every four or six hours, in a typical case of mountain fever, was not unusual in my practice, and Dr. D. W. King, who was in practice there, tells me he often gave a full ounce during twenty-four hours with the best results. Of course, this was in extreme cases ; but, taken with facts known to the older men in practice in the mountains, proves that quinine is generally required in large doses in high altitudes, in any disease accompanied with fever, not only for its anti-periodic effect, but for its sedative action, so often needed to control nervous excitability caused by the unusual electrical conditions in all high altitudes."

The Congress.

We copy the following letter from the *Jour. Am. Med. Ass.*, January 9, 1886, as it clearly demonstrates how anxious the *Medical News* and the *Medical Record* have been to injure the Congress, and to what means they resorted to accomplish this end:

"According to the *Medical News* (of Philadelphia) of December 26, the *Med. Record* gives the following editorial note from the *St. Petersburg Med. Wochenschrift*, of Nov. 21: 'The prospects of the next International Medical Congress, which *was* to meet in 1887, in Washington, have lately, in an unusual manner, been put in jeopardy. The original Organizing Committee, of which, as announced by us in previous communications, *the well-known Surgeon-General of the U. S. Army was Secretary-General*, and to which the most distinguished American physicians belonged, has been retired. This was accomplished through the intrigues and hostility which developed at the last annual meeting in New Orleans. At this time a new Committee was appointed, *under the presidency of a Dr. Shoemaker*, of Philadelphia. This new Organization Committee contains but a few of the members of the previous committee, and *is composed mostly unknown and insignificant physicians*, who inspire no confidence in their capacity for conducting the Congress.'"

"When the *St. Petersburg Med. Wochenschrift* knows no better than to confound '*the well-known Surgeon-General of the Army*' with the officer who was the Secretary-General of the committee of seven, it publishes the value of its condemnation of the new committee as 'composed mostly of unknown and insignificant physicians.' To it they doubtless are unknown. But what shall be said of both the *Medical Record* and *Medical News*, which reproduce this statement about 'the well-known Surgeon-General of the Army' (and not for the first time) without contradiction? SURGEON.

Ninth International Medical Congress—Progress of Organization.

In connection with our editorial, and as an answer to all inquiries as to whether the International Congress will be held, we reproduce the following from the *Official Journal of the American Medical Association*, January 9, 1886:

"Two or three of our exchanges still repeat the assertion that no material progress has yet been made in the organization of the Congress. This is far from being true. On the contrary, the preliminary organization is at this time nearly complete. *First*, notwithstanding all that has been said about *declinations*, a large number of those appointed and published by the Committee on Organization, at first constituted, still hold their places, and for every one who has declined two equally well qualified have cheerfully accepted positions. *Second*, the only important vacancies now existing are in the office of President of the Sections of Physiology, Pathology, and Gynecology, the filling of which has been delayed by the Executive Committee for reasons we have stated in previous issues of this journal.

"Not only is the *personnel* of the organization thus nearly complete, but the proper officers are actively engaged in arranging the work for each Section, and the Executive Committee will doubtless be ready to issue a supplementary circular containing a full programme, early in May next. Already notices of contributions for several of the Sections have been received from prominent members of the profession in Great Britain, and indications favorable for a full European attendance are daily increasing."

The Influence of Temperature upon the Life of the Fœtus and Gestation.

Doré, who has made a series of experiments upon animals with special reference to this subject, contrasts his results in the *Arch. de Tocol.* with those obtained by Runge. His conclusions are as follows:

1. The conclusion of Runge that the temperature of the fœtus is always slightly higher than that of the mother, even when the latter is above normal, cannot in the meantime be refuted.

2. No genuine experiments have ever proved that the fœtus dies much before the mother, but rather that the two deaths coincide, or nearly so, in point of time.

3. A temperature of 41.5° C. does not always cause the death of the fœtus, even when maintained for two hours; while Runge believes that exposure to this temperature, even for a few minutes, must of necessity prove fatal.

4. An elevation of temperature to 43° C. may be endured for a short time without injuring the fœtus or interrupting gestation, if it be reached very gradually.

5. It was found that whether the mother resisted an excessive elevation of temperature, or died from its effects, the excessive temperature alone was insufficient to produce abortion or premature labor.

6. Animals, even of the same species, present considerable difference in the normal

temperature point, and in the rapidity with which a very high temperature is reached, the same rate of increase of external heat being observed in all cases.

The Delirium of Bright's Disease.

It is well that we should know that M. Dieulafoy, in *La France Medicale*, draws attention to the fact that cases of delirium from Bright's disease may so resemble insanity as to lead to their being confined in asylums, Bright's disease not being suspected. Delirium is more rare in this disease than convulsions and coma; and uræmic delirium, when it does occur, is usually quiet, but sometimes it becomes so violent as to resemble acute mania; while in other cases it takes the form of hallucinations of hearing or of vision. It may be only part of a uræmia of which there are other symptoms. But, and it is this which M. Dieulafoy specially emphasizes, it may be the primary, or at least the dominating fact of the case, so that the attack is looked upon as one of insanity. He notes six cases of this kind, one of which was confirmed by a post-mortem examination. Such delirium may occur in both acute and chronic nephritis, in scarlatinal, and also in puerperal forms, so that, as Legrand du Saulle says, puerperal mania may really be a result of Bright's disease. The question of diagnosis is very important, for œdema is wanting and albuminuria may be absent. It is, therefore, on the other accessory signs of Bright's disease that the diagnosis sometimes has to rest. The prognosis of uræmic delirium is less grave than that of convulsive uræmia: for of six cases only one died in the course of the delirium. The treatment employed must be that for Bright's disease and and uræmia, not that for insanity.

The "American Pasteur Institute."

We learn that the certificate of incorporation of the American Pasteur Institute was filed recently in the New York County Clerk's office. The objects of the "institute" are "the gratuitous cure and treatment by the Pasteur system of inoculation, or such variations thereof and improvements thereon as science may develop, of all persons suffering from, or threatened with, or in danger of hydrophobia or any other disease to which the system of inoculation may be found applicable, and the scientific examination of the causes, development, and improved means of prevention of hydrophobia and other diseases through inoculation or kindred methods." The incorporators are Alexander B. Mott, Michael J. B. Messemer, Louis De Pease, Alexander F. Trantard, Charles F. Nirdlinger, Charles Villa, Valentine Mott, and Adolph Corbett. We learn that a company has been organized in St. Louis, Mo., for the purpose of cultivating and using the Pasteur virus against rabies.

The Case of Dr. Graves.

The *Pacific Medical Journal* tells us that Dr. Graves, of California, has been mulcted of eight thousand dollars in a pauper case. The evidence of ten well-known surgeons showed that the doctor intelligently and faithfully treated the case. Two doctors gave an adverse testimony. One of these was nearly eighty years old, and had not read a work on surgery for thirty years. The other confessed that he had no experience in surgery. The doctor had attended the family of the woman bringing the suit against him, gratuitously, for sixteen years. The whole affair is a scandalous outrage upon the doctor, if the facts are fairly represented. The profession of California should lend the doctor a helping hand.

Reich's Hungarian Wines.

For a number of years Mr. L. Reich, of 63 West 11th street, New York city, has devoted his time to the selection and importation of high class Hungarian wines for medicinal use. They are sound and pure, and of the most esteemed vintages. They are free from the harshness which is a detriment to most American wines, and may be recommended to the profession as unsurpassed by any in the market.

Another Cure for Stammering.

A writer in the *Popular Science News* gives the following as a method for the cure of stammering: "Go into a room where you will be quiet and alone, get some book that will interest, but not excite you, sit down and read two hours aloud to yourself, keeping the teeth closed. Do the same thing every two or three days, or once a week if very tiresome, always taking care to read slowly and distinctly, moving the lips but not the teeth."

Packer's Tar Soap.

After trying any number of soaps, we have settled down on PACKER'S TAR SOAP as the best of all, whether as a toilette or a surgical soap. It is remarkably pure, cleans-

ing and healing; it is excellent it is excellent in a large variety of skin diseases, among which we particularly name seborrhœa of the scalp, dandruff, intertrigo and winter prurigo, all of them very common and very obstinate. It contains the balsamic virtues of the pine in a high degree, and is soft and refreshing to the skin. It deserves a wide introduction.

Items.

—A new medical college is announced at Wichita, Kansas.

—An Italian translation of Pepper's System of Medicine is announced as in course of preparation.

—In the *Lancet*, December 5, 1885, is described a case of "election mania," terminating in meningitis.

—The honor of knighthood has been conferred on Dr. James Sawyer, the well-known physician of Birmingham.

—The medical profession will learn with regret that Dr. Squibb has discontinued the publication of the *Ephemeris*.

—After teaching obstetrics more than fifty years in the Medical Department of the University of Georgia, Dr. Joseph A. Eye has resigned.

—Gérard Lague has recorded the useful fact that the acridity of potassium iodide is completely masked when administered in gooseberry syrup.

—A case of death from cocaine applied to relieve the pain of a decayed tooth is reported by Prof. R. Ogden Doremus to the New York Medico-Legal Society.

—In the *New York Med. Jour.*, January 9, 1886, Dr. Horace A. Sherwood reports a case of successful ligation of the common carotid artery for traumatic aneurism.

—It is announced that the *Analectic* is hereafter to be conducted by Dr. R. W. Amidon, and marked improvements are promised in the character and arrangement of its articles.

—The *American Practitioner* and the *Louisville Medical News* have been consolidated. The new journal is to be issued biweekly, and is to be edited by the former editors of the constituent journals.

—Dr. Brendal (*Peoria Medical Monthly*) says: "The aim of the practice of medicine may be lucre or bread and butter, but if it be not combined with love of study or the humane desire to do some good, it is the most despicable business imaginable."

—At a recent reform meeting in New York, it was stated as a matter of fact, that the State of New York had expended more than one million three hundred thousand dollars in the support of four generations of the descendants of one prostitute.

—In the *Lancet*, December 5, 1885, Dr. Sinclair reports a case of hemorrhage into the substance of the spinal cord after severe expistaxis; no family history of hemophilia; sudden paralysis; intense anæmia; coma; death in four days; necropsy; remarks.

—The widow of the Dr. F. Jenks, of Philadelphia, has given in trust to the College of Physicians of Philadelphia, $5,000, the interest of which is to be tri-ennially given as a prize for the best essay offered in competition upon some subject connected with obstetrics and gynæcology.

—A note in the *Boston Medical Journal* says that a prominent Boston gynæcologist has been sued for $10,000 damages by a pauper patient. She claims that he operated upon her against her will, and that the operation was unnecessary and improper, and she was discharged from the hospital at an unsuitable time.

—Dr. J. M. Hayes, of Oxford, N. C., reports a case of Cæsarian section after the death of the mother, in the *North Carolina Medical Journal*. As soon as he satisfied himself that the mother was dead, he quickly opened the abdomen and removed a living child from the uterus; the child was eight and a half months old, and bids fair to live.

—The first extirpation of the larynx by a French surgeon is reported by Dr. Leon Labbé, *Bull. de l'Acad. de Méd.*, 2d series, Tome xiv., No. 12, and *Revue des Sci. Méd.*, October, 1885. It was a case of sarcoma of the larynx. The patient made a good recovery; no complications were noted, and his condition, fifteen days after the operation, was very satisfactory.

—According to the *St. Petersburger Medicinische Wochenschrift*, Professor Albert, of Vienna, has lately taken up the cudgels in behalf of the practitioners, who, he plainly implies, are handicapped by having to struggle against a great number of men who are armed with the prestige of extraordinary professorships. The honor of being appointed to one of these positions is not great, but it serves *ad captandum vulgus*, being a sort of recognition from the university, and it certainly ought not to be placed indiscriminately in the hands of men who are unscrupulous enough to use it as a stepping-stone to popular favor.

JENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle pleasantly flavored. Retail $1.00. All of it pure pepsin.
See page 10.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin*," must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also affirmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Clinical Lecture.

LEAD-POISONING.

BY J. M. DACOSTA, M. D.,

Prof. of the Practice of Medicine at the Jefferson Medical College, Philadelphia.

Two cases, illustrating the extraordinary differences in individuals as to susceptibility, symptoms, and manner of attack, were shown.

Case 1. Patient, a man aged forty-five years, was engaged in working at his trade, which was that of a painter, for the past twenty-eight years, during which time he was perfectly healthy, till two years ago, when he was attacked with colic and constipation, lasting for three weeks. He treated himself with salts, and recovered. Was well till one year ago, when there appeared upon the arm a squamous eruption, accompanied with burning and itching-pains in the joints, severe cramps in calf muscles, wrist-drop, burning sensation in soles of feet, and impaired vision. Lately he has suffered from giddiness and tremors. Tremors began last January, and are better now. There is marked flexion of the fingers; considerable loss of flesh; wrist-drop came on suddenly. On examination of his heart, I find a rather feeble first sound, but no murmur. The characteristic blue line is on the gums; the tongue is flabby, and marked with the teeth. His walk is unsteady; muscular contractility is impaired; worse, however, on the left than on the right side. All power over the extensor muscles is lost, and even the joints seem to be implicated, for the fingers are slanted, as we observe in rheumatoid arthritis. There is marked atrophy of thumb muscles, and between the metacarpal bones, giving the appearance of subluxation, and the most marked slant I have ever seen. His grasp is feeble. General cutaneous anæsthesia, but most marked on the right arm. There is, in brief, double paralysis of the whole muscular system, coming on, it is to be be observed, after a quarter of a century's work with the poison.

Case 2. This patient, a man aged forty, worked three years in paint and handling metallic lead. Only six months after beginning this work he had an attack of colic and constipation, from which he recovered; but nine weeks ago he had another attack which lasted till his admittance into the hospital. He, too, has the blue line on gums. His constipation is easily overcome with sulph. magnesia. This patient has no pains in the extremities, or elsewhere; no wrist-drop, no atrophy of muscles; he has a good grasp; cannot fully extend the hand, but states that this power was never great with him. No cutaneous anæsthesia, but he is strikingly *anæmic*. Heart examination reveals a faint murmur at the apex, systolic in time. At the right base, no murmur can be heard, and the second sound is well marked; also at the left base, though not as well as at the right. The murmur is a *blood murmur*. It may be anæmic, or the beginning of valvular trouble, due to endocarditis.

Let us briefly compare these two cases:

No. 1 withstood the action of the poison for twenty-five years.

No. 2 easily succumbed in three years.

No. 1. The poison has a profound hold upon the nervous and muscular systems; the cutaneous anæsthesia, especially in the soles of feet, speaks of symptoms found in bad cases.

General paresis, most marked in extensor groups; joint implication, associated with atrophy, giving great deformity. Cerebral symptoms—headache, impaired vision, etc.; mind wandered when first attacked; delirium, among the consequences of lead-poisoning when affecting the brain. But no anæmia exists; rather the man is flushed.

No. 2 presents *none* of the above-named symptoms. The poison has affected more particularly the *blood*, producing extreme *anæmia*. When the blood is affected, other tissues, as in this case, have escaped damage, and we will not look for other, as nervous symptoms, in the future.

In both, however, existed colic and constipation. In both was present the characteristic blue line of the gums, and the flabby tongue marked with the teeth. In No. 1 the constipation was obstinate, while in No. 2 it was readily overcome.

The prognosis in both cases is good: they will recover; both will be able to return to their work. Case 1, however, will never recover complete use of his hands. Case 2, under treatment, will completely recover.

Treatment.—In so far as their conditions agree, so shall their treatment. They then diverge. Both are poisoned by the same substance—*lead.* This must be eliminated from their systems. Sulphate of magnesia to act freely on the bowels, and sulphuric acid in small doses. The sulphates are useful in counteracting the influence of lead; but this is not enough, we must eliminate. For this purpose, no remedy compares with iodide of potassium. Nor is this remedy limited to lead poisoning. In zinc and arsenic, and many other forms of poisoning, iodide of potassium is most efficacious. But here in lead poisoning, it is thought supreme. It eliminates the lead in the soluble form of *iodide of lead.* Let its virtue be what it may, its action is good provided it be used in large doses—at least one drachm per day.

For case 1, therefore, we will prescribe large doses of the iodide, and in addition to this, on alternate days, $\frac{1}{60}$ grain of strychninæ sulph., administered hypodermically, and daily faradization of extensor muscles.

Case 2. Here the leading, in fact almost the only symptom, is anæmia, produced by the same poison. Hence, while we recognize the presence of lead in the system, and endeavor to eliminate the same, we will have due consideration for his anæmic condition. We will give to him only one-half drachm doses of iodide of potassium per day, together with syrup of the iodide of iron.

These two cases show all the interesting points of lead poisoning, and the strikingly different manner in which the same poison may affect different individuals.

The question is sometimes asked, Is atrophy due to the action on the nervous system, or are the muscular structures primarily affected? Lead acts upon the muscle extremities themselves, quite irrespective of the nervous action; hence, it is not purely nervous; the muscular nutrition is interfered with, and curiously affects most the extensor muscles.

Communications.

SOME OF THE COMPLICATIONS OF TYPHOID FEVER.*

BY JAMES B. WALKER, M. D.,

Of Philadelphia.

"Perhaps the novice in medicine, bearing the blushing honors of commencement day thick upon him, feels a greater confidence in his ability to wrestle manfully with typhoid fever than with any of the other of the multitude of diseases for whose mastery he has been endeavoring to equip. This confidence is, no doubt, born of the intimate knowledge of typhoid fever, and the regularity and simplicity of typical cases of the affection, as elucidated by theoretical lectures upon it, as well as by the classical descriptions of it in text-books of medicine. But his overweening confidence is apt to experience some variation as his own experience ripens (?)—no, I dare not say *ripens*, for I doubt if one's experience is ever ripe with typhoid fever; let me rather say *widens.* A few cases which will not tally in temperature chart with Wunderlich, assure him that typhoid fever is like most other diseases, great in its variety, and from a mild form of only a few days pyrexia, it grades to severe forms, lasting as many weeks. His confidence in manipulating it to his own behests is apt to find early decadence in a practical experience, which usually does not require many years for fruition; and as complications and sequelæ, new and diverse, present themselves with each succeeding year, he learns, at last, to look upon this disease as one of the most uncertain, in a prognostic sense, with which he has to cope; and to watch most sedulously even the simplest case, for the earliest manifestation of evidences of aggravation or complication; and is not truly rid of all anxiety until the patient is not only well ad-

*Read before the Philadelphia Clinical Society.

vanced towards, but has thoroughly entered upon convalescence.

"An experience with a few of the rare forms of complications emboldened me to bring the subject before you in order that, peradventure, our conjoint experience may help to widen our knowledge, and make us better able to battle with a disease possessing such superabundance of duplicity.

"*Excessive temperature* is one of the earliest complications. An evening temperature of above 104° F., if repeated, and especially if not followed by a decided morning remission, should be considered as an unnecessary pyrexia, demanding treatment. Antipyretic treatment should not be instituted for a less marked pyrexia occurring during the normal course of the disease, and the use of internal antipyretics for a lower temperature is very much to be deprecated. Simple sponging with cold water, or with tepid water alone or medicated with some volatile substance, vinegar, alcohol, etc., may of course be used for even the mildest cases, being both cleanly and grateful; but the deprecation refers to the indiscriminate use of antipyretic doses of quinia and other active agents, which have a prejudicial as well as beneficial possibility. I will go a step further, and advise the use of such spongings even in the severer forms of recent occurrence, or where internal remedies are contraindicated, as in cases of irritable stomach, in which cases the volatile principle may govern us in the choice; or the direct use of ice-bags or ice-spongings may be resorted to, or the cold pack. Of the antipyretic remedies administered internally, I have had extensive experience with but two, viz: quinia and antipyrin. In private practice I have generally resorted to quinia in doses varying according to the urgency and severity of the pyrexia; and as this remedy is a local irritant, and its administration by the mouth is or may be decidedly detrimental, and as its administration for tonic purposes in suppositories has proved so desirable, I have been administering it in this manner for its antipyretic effect, with at least as much satisfaction as when administered by the mouth, and with much advantage to the stomach and intestinal wall. I order suppositories containing grs. x. of this agent and gr. ss. ext. opii, administering at night, night and morning, or night, morning and noon, as the case may be. In pyrexia of moderate severity, arising from transient causes, this agent is all that is needed, and proves very efficient, as more rapidly reducing the temperature to that compatible with safety than would spontaneously occur in such cases. But one early learns the utter non-utility of quinia in many cases of severe pyrexia, where such an agent is most sorely needed. I believe such cases are usually those in which, owing to the virulence of the poison, either from quantity or quality, or from the susceptibility of the patient, or from other equally occult causes, the febrile character of the affection is especially marked, whereas the intestinal and other symptomatic lesions might be quite mild. In such cases, marked by *high fever* and but little else, I have usually found quinia 'a delusion and a snare,' even when administered in large doses by the mouth.

"In the wards of the Philadelphia Hospital where a large number of cases of typhoid fever are usually under observation, the new antipyretics have successively been given a trial, with, so far as I am able to learn, decided preference for antipyrin. This new agent, a derivative of aniline, given in doses of gr. xx., repeated once, if necessary, will reduce the fever in the vast majority of cases, and that with more certainty than any other antipyretic with which I am familiar. In cases where the stomach is irritable it may be administered in solution by the rectum. Gr. xx. by the mouth and gr. xxx. by the rectum need not usually be repeated, and will, in the vast majority of cases, promptly reduce the temperature from 2° to 4°. In from twelve to eighteen hours it will rise again, sometimes reaching in twenty-four hours a height equal to that from which it fell the day before, requiring another dose, to be repeated in some instances for two or three consecutive days. But as this repetition is without unpleasant result, there is no objection to it, whereas the advantage gained by the lessened pyrexia, for even a few hours, is not to be despised.

"In the temperature chart which I here show you of a case of typhoid fever, with relapse, the records show a reduction of temperature from 104.4° at 12 m. to 100.4° at 9 p. m. on the forty-second day of the disease and the fifth of the relapse, owing to the administration, per rectum, of gr. xxx. of antipyrin. The following day gr. xxx. by enema at 6 p. m., when temperature was 104°, was followed by reduction to 99.4° by midnight. Two days after, temperature 103° at 9:30 p. m., caused it to fall by 12 p. m. to 100.2°. The effect is more certain and rapid than that of quinia, but I believe it is not so permanent; usually in twenty-four hours it again creeps up toward the point whence it fell.

"This patient had his first normal or subnormal temperature on the twenty-eighth day of the attack, the temperature the evening before being 102.6°. The relapse began nine days later; evening temperature 101°. The following day, evening temperature reached 104°. The highest temperature in the first attack was 104.6°, which it reached on the eleventh day and again on the twenty-third. The highest temperature of the relapse was 106.8°, which was reached on the ninth day thereof. A temperature of below 105° and 105.5° was reached on the third, tenth, fourteenth, and fifteenth, and below 105.5° and 106° on the eleventh and twelfth day of relapse. The first normal or subnormal temperature of relapse was reached on the fifteenth day thereof at 5 a. m., 97.6°, the temperature the night before reaching 105.4°, fifty-two days from the commencement of the disease; and for the previous three and subsequent four days, the difference between the morning and evening temperature was from 4° to 5°.

"This is the only case in which I have found it *necessary* to administer antipyrin in this way, although it may be *desirable* to so administer it, except when by profuse diarrhœa or other cause the use of the rectum, for such purposes, is contra-indicated. The temperature records of the Philadelphia Hospital will verify this record repeatedly as to the promptness and efficiency of antipyrin *as a rule*. Of course, exceptions occur, but these exceptions are like destructive conflagrations, which defy all efforts towards extinction, and which only prove the inability of the antagonistic power to cope with them, but do not argue against the general utility of such power. So, in spite of two cases of excessive pyrexia in typhoid fever, occurring in the wards of one of my colleagues of the Philadelphia Hospital, in which antipyrin proved absolutely inert, I have no doubt of its superiority over quinia in this regard, nor of the appropriateness of its title of *antipyrin*.

"I have used resorcin in but two instances, and inasmuch as it seemed to induce nausea and vomiting in one of these, I have not since resorted to it. In only one instance have I a record of a similar effect with antipyrin, and that was in one of the two cases of excessive pyrexia above referred to, in which it proved ineffective, and in which it had been given in large and repeated doses.

Thromboses have long been recognized as amongst the serious and, when located in the heart, the most surely and rapidly fatal of the complications of typhoid fever. I have had two cases of *femoral* and one of *iliac* thrombosis as complications of the period of convalescence, and this after protracted illness.

"Dr. H., who had an unusually protracted prodromic period of from four to six weeks, during which time he had thought himself suffering with malaria, and kept on with his work, visiting his patients, some of whom had typhoid fever, two or three of whom died. During this long period he had no appetite and ate but little. The day I first saw him he had visited several patients, and at that time, 7:30 p. m., his temperature was 104°. Although he was sure he had not typhoid fever, he was put to bed and ran a fair course until convalescence, with occasional rather severe diarrhœa and some intestinal hemorrhage. One or two days after the fever had been normal in the morning, though the evening temperature still 'ran up,' his attendant, contrary to explicit directions, allowed him to sit up to stool. At my next visit, he complained of a pain along the right femoral vein, from the groin downwards, which was tender to pressure, and gave other evidence of phlebitis, resulting in an excessive phlegmasia dolens, but which subsided only to be followed by a thrombosis of the left iliac and femoral veins, whose onset was accompanied by a shock so severe as to threaten to prove fatal for thirty-six hours. The subsequent phlegmasia was not so excessive in the left as it had been in the right leg, and convalescence seemed again establishing, when a recurrence of febrile symptoms, with diphtheria but without tympanites or return of rose spots, proved too much for him. In this case the thrombosis was attributed to a feeble heart, combined with a hyperinosis, both consequent upon the prolonged period of fasting prior to the outbreak of the fever, and the diarrhœa, hemorrhages, and fever of the attack itself, and was apparently *directly* due to the position allowed the patient at stool just prior to its occurrence.

"The third case, that of Dr. S., occurred also after a protracted attack, in which the primary fever lasted for five weeks, and in which the patient, not a milk drinker, was fed largely on meat broths. This patient was badly nursed, and no doubt was allowed to dictate and order her ways and those of her nurses, even though counter to those of the physician in charge, although, of course, entirely without his knowledge, or his means of knowing, as events proved, necessitating the dismissal of the nurse and the employment of one skillful and obedient, whose arrival was immediately followed by

a marked change for the better, and a response to remedial measures which before had been wofully absent, no doubt due to their non-administration. In both these cases I believe the result was largely due to the fact that the patient, being a physician, was allowed by the attendant to tamper at pleasure with the orders of the attendant and responsible physician. The moral of which is, under all circumstances in typhoid fever, have a nurse on whom you can rely to carry out your orders unmitigated, and especially if the patient is a doctor of medicine. This patient, though presenting a decided femoral phlebitis with its cord-like character, pain and tenderness, did not have a severe phlegmasia. The thigh swelled, perhaps, to twice its circumference, but the leg was less swollen, and the foot still less. It responded nicely to treatment, although the tenderness and rigidity of the femoral lasted for some time and rekindled twice, but was promptly met and controlled. The treatment consisted in the use of *position*, patient recumbent, with limb raised, that gravity might assist the blood to leave it; *warmth*, insured by large hot-mush or potato poultices during the cold stage, followed by a cotton or flannel jacket until the pain subsided, and the use of a bandage from the toes on the patient leaving the bed during convalescence, if there was any tendency to swelling or return of pain. Besides this, an ointment of belladonna, or belladonna and mercury, or of mercury alone, was used at first, and during the acutely painful stage, followed by iodine applications, which were kept up at intervals until all swelling and hardness had disappeared. Dr. Hutchinson (Pepper's System of Medicine) recommends hot cloths saturated with hot vinegar and water. Internally ammonia was given freely in the form of the carbonate and aromatic spirits, both for the effect on the heart and against shock, as well as with the theoretic idea of increasing the alkalinity of the blood and lessening the danger of a clot. Absolute quiet was, of course, enforced, lest thrombosis, cardiac or other, might result, or that a portion of the clot already formed might be broken off by the movements of the affected limb and distant embolism result.

"Although the records of thrombosis in typhoid fever make of it not a severe lesion, only two of thirty-one cases collected by Liebermeister, and three of seventeen collected by Murchison, having proved fatal, and all of Hutchinson's cases (number not mentioned) have ended in recovery, yet it seems to me that we must look upon this complication as the representative of a very serious and critical state of the circulating fluid, and one in which extremest care must ever be taken to ward off, if possible, serious if not fatal consequences.

"*Pneumonia*, either croupal or catarrhal, has fallen under my observation a number of times. The most markedly severe as well as successful case was that of R. C., about twenty years of age, unmarried. In convalescence, a bronchial catarrh, which had existed throughout a decidedly severe attack of typhoid fever, involved the lobules of the lungs, especially the right, in a quite extensive though diffuse secondary inflammation. Drs. Wm. Pepper, Hanna T. Croasdale, and Amy S. Barton, united with the author in this diagnosis, and a very grave prognosis, considering all the elements of the case, was the result of our deliberations. The patient, however, survived, his lungs cleared up entirely, and he has since successsfully passed rigid examinations in old line life insurance companies. In this case, turpentine gtt. xv.–xx. of the oil, repeated every 3 or 4 hours, was the especial stimulant resorted to. This has long been my favorite pulmonary stimulant in typhoid fever. The reason for its choice was, I admit, pure theory. If the delirium, typhoid state, hebetude, etc., of typhoid fever be due, as claimed by Murchison, to the presence of the results of nitrogenous waste in the blood, I argue, why add to the nitrogenous waste by administering ammonia in any form? I may say that in the above, as in many other cases of typhoid fever with catarrhal complications of the lungs, the result of a resort to turpentine as a substitute for carbonate of ammonia has proven its usefulness. But when at the present day carbonate of ammonia is vaunted as of specific virtue in typhoid fever, Simon pure or complicated, my theory may prove mythical, although the results of my experience with turpentine remain the same. In, however, the croupous variety, the case is different. Here, from the inception of the crepitant râle to the disappearance of all evidence of solidification, I believe carbonate of ammonia to be our sheet anchor, whether the explanation of its benefit rests on its prevention of solidification of the exudate, as claimed by Bartholow, or on its influence on the heart, the vaso-motors, and the respiratory centres, or on all combined. In doses of gtt. viij. in syrup or mucilage of acacia, well diluted to rob it of its acidity to throat and stomach, and repeated every 2 or 3 hours, it furnishes with whisky, liquid food,

and jacket poultices, an aid which is worthy of great confidence and praise.

"The onset of croupous pneumonia is sometimes so insidious that its approach should be sedulously anticipated in cases of decided severity. It will not do to expect marked changes in the course of the disease by its occurrence, as the temperature chart which I now show you will testify. The onset of croupous pneumonia, as a primary disease, is marked by most decided symptoms, which are usually pathognomonic. But in its stealthy approach as a secondary phenomenon, it is sometimes not suspected until well advanced. The respiratory difficulty, combined or not with more or less marked cyanosis, due to circulatory disturbance, is more suggestive than any rise of temperature, and should suggest the examination of the lung which the position of the patient has placed lowest and most inaccessible, as well as that which can be examined without disturbing him. In this form carbonate of ammonia is the remedy of remedies. It should be given in full doses, repeated at least every 2 hours. Alcoholic stimulants are usually also required.

"*Convulsions*, epileptiform in character, may occur in typhoid fever. Dr. J. C. Wilson, in his work on 'The Continued Fevers,' refers to them as follows under the head of symptoms referable to the nervous system: '*General convulsions* are rare. They occur with greater frequency in children than in adults. It would appear that, although occasionally associated with albuminous urine, they also occur independently of that condition, but are, in all instances, of the greatest prognostic import.'

"Dr. Jas. H. Hutchinson, in his article on typhoid fever in Pepper's System of Medicine, says: 'General convulsions are not common, but occasionally do occur. Although a very grave symptom, they are not invariably fatal. Recovery took place in one of two cases which came under my own observation, and in four of the *six* recorded by Murchison. They are not always associated with an albuminous condition of the urine. In neither of my cases was there albuminuria, and in only one of the four of Murchison's cases in which the urine was examined was it present. In one of my cases—the fatal one—the convulsions seemed to have been induced by giving the patient improper food; in the other, no cause could be discovered.'

"These authors both refer to this symptom under the head of the clinical history of the disease. With such convulsions I have had no experience. As a sequel, however, I have observed them on two occasions.

"Case 1. G. A., age 22 years, traveling salesman, taken sick with chilliness and fever while "on the road." Returning to Philadelphia, I found him, October 2, 1873, in bed with a history of several days' illness. Temperature 103.5° F.; severe headache, and with rose spots already on abdomen. The subsequent course of the attack was marked by a more than ordinary exacerbation of temperature; repeated attacks of epistaxis the first few days; three quite profuse intestinal hemorrhages during the third and fourth weeks; one attack of pulmonary œdema on the 22d day in bed, with associated symptoms of profound collapse, and threatened imminent dissolution for several hours; delirium and continuous irrationality for upwards of four weeks. On morning of the thirtieth day in bed, when the temperature was sub-normal (97° F.), and after the morning temperature had been between 98° and 99° for two days, and immediately following the first normal evening temperature, without appreciable provocation, he was seized with an epileptiform convulsion, which was general, lasted for several minutes, and was followed by stupor. There was no subsequent pyrexia. There had been no thrombosis anywhere, nor was there any albuminuria at the time, nor subsequently; the weak heart and profound anæmia, from a prolonged and severe attack, alone suggested a cause. Prof. Pepper saw the case in consultation, and agreed in the causal diagnosis, which seemed to be verified by the subsequent history. Increased stimulation for a few days, with the use of sodium bromide for 24 hours, was followed by uninterrupted improvement to complete convalescence. The patient has had no convulsions or other nervous phenomena since his recovery, nor had he ever a convulsion in his childhood. I consider it a case of post-febrile convulsion due to cerebral anæmia.

"Case 2. Dr. E. M. S., woman, aged about twenty-five, was taken with typhoid fever, July 28, 1885. The initial symptoms were markedly cerebral, following a walk in the sun on a very hot day, inducing Dr. James Mitchell, who was called to the case in my absence from the city, to attribute the disease to heat-stroke for the first few days. The fact that in a family with whom she had stopped for two days, ten days previously, in a neighboring city, three cases of typhoid fever developed at the same time, together with the subsequent clinical history of the case under observation, which ran a typhoid course (though protracted), left no doubt in our minds of the true nature of the ailment.

"The cerebral symptoms of the first few days subsided, and except for occasional delirium, no nervous symptoms afterward developed until convalescence. During the attack, this patient had phlegmasia dolens, due to femoral thrombosis, and is one of those already referred to. About the tenth week, when the patient had been sitting up for some days, gradually gaining strength, after semi-reclining at a front window for two hours, and while the nurse was absent from the room, she proposed to her brother a walk back to her office, in the back of the same story, with a half flight of steps to descend in order to reach it. This was her first visit so far from her room, and this after her brain had been robbed by gravity by her position for the past two hours. On reaching her office she asked for a drink of water, as she felt faint, and sinking into a chair, fell into a convulsion, epileptiform in character, and quite decided, lasting some minutes, and terminating in a stupor. Her tongue was bitten during the attack. She was at once returned to bed, restoratives were administered, and she again improved, but several small and some severe attacks of a similar nature followed; sometimes two or three attacks, wherein she simply lost consciousness and twitched, but slightly, would occur in a single day. She would complain of a feeling of impending death from cardiac distress in the period immediately anticipating the attack, corresponding in time and duration to the epileptiform aura. Persistent use of small doses of sodium brom. (about forty-five grains daily) with tonics and stimulants, have carried the patient beyond not only these recurrences, but, also, I believe, the danger of their return. This patient had never previously, even in infancy, had a convulsion of any sort. The first was attributed to the cerebral anæmia, sufficient cause for which existed; and most of the subsequent ones were due, apparently, to an easily-formed habit in an excitable and debilitated nervous temperament.

"*Impairment of intellect* sometimes exists as a sequel of typhoid fever, and has been at times a matter of serious moment in a prognostic sense. It is most apt to occur in cases with well-marked nervous phenomena during the course of the disease. As the other symptoms subside, temperature, pulse, and respiration becoming normal, the tongue cleans, appetite returns, but days, even weeks, pass with imperfect cerebration persisting. Lucidity may sometimes appear momentarily, only to verge into mental darkness. Mania active, simulating the delirium tremens from alcohol, may occur, as in a case which I recently saw in consultation. Such a case may suggest the possible existence of a more or less permanent lesion, which would leave persistent traces in the subsequent intellectual life. But against this prognosis stand the records which show the ultimate recovery, almost invariably, of full mental vigor, though it may require weeks or even months to bring the consummation. No wonder the cerebral functions are impaired, with every tissue in the body suffering from prolonged supply of impoverished and poisoned blood. With the rejuvenation of the sources of blood supply, and the avenues of blood purification, the current will become less and less corrupt, and more and more nutritious and healthy tissues will result, cerebral and glandular, as well as muscular. In such cases strychnia and arsenic, for their influence in cell nutrition, aid materially in forwarding the desired result, and should not be overlooked in the employment of iron, simple bitters and the other grosser tonics, which, of course, have their service as well.

"Other exaggerated symptoms, complications, and sequelæ, have, of course, fallen under my notice, and might justly claim attention in this paper; but as it makes no pretensions to exhaustivenes, and it has already grown considerably beyond what was at first intended, I will tax your time and patience no further."

FRACTURE OF THE SKULL.*

BY T. D. BROSE, M. D.,
Of Evansville, Indiana.

The doctor presented a patient, a child who had been kicked in the head by a work horse heavily shod, while at play in the street, and picked up wholly unconscious. The doctor, in company with Dr. W. D. Babcock, saw the child one hour after the accident. He was still unconscious, had a rapid feeble pulse, and widely dilated pupils. Beneath the scalp was much effusion of blood, just in front of the anterior fontanelle. There was a lacerated wound, but no fracture of the bone beneath. Along the right parietal eminence there was another lacerated wound, and a probe introduced here passed rapidly into the cranial cavity, and revealed a single fracture of the right parietal bone, with much separation of fragments. The prognosis was made that the child would live but a short time. Nothing further

* Abstract of paper read before the Mississippi Valley Medical Society.

being indicated, we applied cold cloths to the head, and gave a few drops of brandy. The next day the patient regained consciousness and was able to talk, but had complete paralysis of the left side of the face, and left arm and leg. Above each eye a bluish ecchymosis was noticed, but no subconjunctival hemorrhage. Fever, great listlessness and irritability, occurred. The bromide of potash 10 grains, every two hours, was prescribed, and the cold applications were ordered continued.

On the third day the temperature became normal. On the sixth, a chill and fever occurred. On consultation an exploratory incision was determined upon to liberate the retained pus, and see if there was depressed bone and liberate the same. The incision revealed the presence of a depressed part of the parietal bone. The adhesions with the dura mater were severed, and the bone removed with the forceps. The fragment embraced both tables of the skull, was wedge-shaped with apex posterior, and about two inches in length. Much pus escaped from the cortex of the brain after the incision. The entire length of the fracture could now be examined with the finger. The patient suffered very much from the operation, and was pulseless.

In four months the boy had fully recovered his former health and activity. An opening still exists in the skull, which by actual measurement is $\frac{3}{4} \times 5\frac{3}{4}$ inches in its greatest measurement, in the middle of the parietal bone. Pulsation is distinctly seen through the cicatrix.

Dr. R. W. Amidon, of New York, in the *Med. News* of Philadelphia, gives a good indication for opening the skull. "An injury of the vault, the marks of external violence however slight, provided there be coma, aphasia, hemiplegia, or hemispasm of the lower part of the face, of the arm, or leg, all three constituting hemiplegia, whether or not accompanied by chills, fever, headache, or vomiting. General epileptic convulsions do not constitute so good an indication for operation. Every case of compound fracture of the skull, whether there be cerebral symptoms or not, cases in which after the lapse of months, or years even, unmistakable symptoms follow an injury of the head. Atrocious and uncontrollable headache, particularly of localized monoplegia, hemiplegia; seizures of general epileptic attacks, if they have an aura pointing to a localized lesion. In addition to the bone, the dura mater should be opened in all cases where exploration with a hypodermic needle discloses the product of a purulent inflammation, or a great deal of fluid under it. In all cases in which a serious brain lesion is suspected, but cannot be proven otherwise."

There are two conditions which when present demand an immediate resort to the trephine. One is when the fracture is of limited extent, and when there is reason to think from the situation or the occurrence of monoplegia, monospasm, or hemiplegia, that a splinter from the inner table may have penetrated the motor tract of the cerebral cortex. The other case is one in which compression is caused by an accumulation of blood between the dura mater and cranium. Such an accumulation may result from a wound of the large venous sinus, but in the large majority of instances it depends on a wound or laceration of the middle meningeal artery. The accident is most frequently accompanied by compressed fracture, but it may be met with in cases of simple fracture. While believing that the trephine is to be recommended while the depression is marked but not of great superficial extent, and in all cases of punctured fracture where there is reason to suspect that the internal plate is extensively splintered or depressed, the doctor is strongly opposed to active interference where the fracture is of great extent and where the depression is not limited or abrupt. It is true that those cases are usually fatal, but I am sure nothing can be gained by the operative procedure that would be involved in any attempt to remedy the displacement, aside from those cases where the brain has suffered irreparable damage. He thinks that in many cases success will be attained by a careful antiseptic treatment of the wound, such as is recommended by Lister in the management of compound fracture of the lower extremity.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Prof. H. C. Wood, M. D.

Insanity.

Dr. Wood very truly remarked that the majority of graduates in medicine know nothing about insanity, with cases of which they are just as likely to be brought into contact as with cases of any other disease, and he proposes to devote several lectures to the subject. It is important for medico-legal purposes to know what is meant by insanity, yet it is very hard to get an accurate defi-

nition, to draw the border line, since we may encounter every grade of mental unsoundness from sanity to insanity; it is hard to say where sanity ceases and a man becomes insane. If we could see the bile distilling from the liver and the thought from the mind, we might in each instance be able to say when each organ had become deranged. There is no sharp line between mere "cussedness" and total depravity, between eccentricity and insanity. Any line that may be drawn would necessarily be an arbitrary one. Dr. Wood would define insanity as "a diseased condition of the mental functions, in which the disease has progressed so far as to be beyond the power or will of the patient to control the manifestations;" provided such loss of control is not due to some poison in the blood. He related a recent case in Delaware, where a man had for some time been drinking heavily, and he compelled his little son to get him a gun, with which he killed his uncle and one of his sons, and tried to kill the other. When under the influence of alcohol, this man had delusions; when sober, he was sane. This man was not legally insane, but Dr. Wood believes that he was irresponsible for his actions, and testified in court that, in his belief, the man was insane. In order that we may be able to recognize the abnormal functions that constitute insanity, we must have a clear perception of the normal functions that are deranged, just as with any bodily disease. He commences by dividing the functions of mind into—

1. Will.
2. Intellect.
3. Emotion.

The duty of will in every normal brain is to control action, to control emotion, to weigh reason. Intellect enables us to make up our minds; it includes the power of reasoning, of memory, while emotion includes the passions, as anger, fear, etc. In insanity we must look for a disturbance of these functions. There are some cases where the will-power is chiefly affected; a person cannot do certain things because his will-power is impaired. He had a woman for a patient once who could not walk forwards; there was no lack of power, but the will to command the movement was wanting. This impairment of will-power plays an important part in many forms of insanity, and in rare cases it is the basis or chief manifestation.

The "emotions" may be depressed or exalted. When depressed, the patients exhibit fear, sorrow, etc., and we have the form of insanity known as *melancholia*. When they are exalted, we have, so to speak, the opposite condition from melancholia. Some cases of insanity are entirely due to emotional disturbances. When a man controls his temper, he uses an inhibitory force, just as, physically, the pneumogastric nerve exerts an inhibitory action on the heart; and when he works himself up into a passion, he excites this emotional centre. When the will no longer controls a man's emotions he is emotionally insane. Such a thing as emotional insanity, Dr. Wood very emphatically asserts, does exist, although the Supreme Court of this State (Pennsylvania) does not recognize it; but with it there is generally to be found associated derangement of other functions.

In intellectual insanity (dementia) there is no intellect at all; all functions are more or less disturbed. In some cases there may be considerable preservation of the intellectual faculties, a man may not be insane everywhere; to point which, he cited the case of a man who had been confined in Kirkbride's Insane Asylum for years, yet who, while there, managed an estate of three or four hundred thousand dollars with signal ability.

An insane man may be controlled by—

1. Hallucinations.
2. Illusions.
3. Imperative conceptions.
4. Morbid impulses.

These are the four branches of intellectual derangement. A morbid impulse is something which arises in the mind and causes the man to act against his judgment and his will. Most of us have some element of this morbid impulse in us, as witness the great desire among some to cast themselves down when they ascend great heights, and similar impulses, such as destruction without reason, etc. When they are so strong that a man cannot control them, then he is insane. He related the case of a patient, who, when walking along the street, always had an *almost* irresistible impulse to strike in the face all whom he met. This man had no other manifestation of mental derangement, save this absurd desire. He was engaged in a large railroad office in this city, and just after the last Presidential election (he took a great interest in politics) he was so worked up that going to his office one day, he was seized with an almost irrepressible impulse to "*clean out*" the whole building (there were three or four hundred men there employed); and it was only by hastening to Dr. Wood's office, and submitting his will to the control of Dr. W.'s, that he was saved from making a fool of himself. This man was on

the border-line of insanity. Several days in bed and prolonged sleep by opiates brought him into better shape. This abnormal condition, usually comparatively mild, was intensified by excitement and fatigue. There are many men who realize that they are subject to these impulses and also realize their inability to resist them, and are willing and anxious to be placed under restraint in asylums.

Imperative conception is sometimes associated with morbid impulse, but differs from it. It is an idea that takes hold of the mind and leads to certain habitual actions without reason. Dr. Wood now has a man under his charge, who, when a boy of eight or nine, going to school, commenced to pull up the lappel of his coat, "hiking" it up, as it were; he was reasoned with and punished for this action, but all to no purpose. He next commenced to rub up and down the sides of his coat with the coat sleeves; this practice lasted for years. Then came on the imperative conception that he was in danger of personal contamination, and he could not be induced to touch the outside of his coat; some one else had to take it off for him. He then got the idea that he could never complete an act. He is rational, his memory is good, and he attends actively to business. He reasons about his condition, recognizes the absurdity of it, but argues his inability to resist. If he lays down a sheet of paper on the table, he must get it straight, and *it never is straight;* thus, for hours, he will fool with this sheet of paper, never satisfied that he has it right. He will often consume two hours at night getting his coat off (without touching the outside) and getting it *straight* on the chair. He realizes his infirmity, and claims that he resists it, but compares this resistance to one endeavoring not to breathe; he is ultimately *forced* to yield. The most common form of this affection is the fear of contamination by filth. Dr. Wood has a female patient who will have no money about her save crisp, clean, new bank-notes; she will not touch her outside dress, and is continually washing her hands; she knows they are not dirty, but cannot control this impulse. She would starve to death in a room rather than touch a knob to open the door. On one occasion, when giving her a prescription, he laid the paper on the arm of her chair (to test her); she would not touch it, for "you know, doctor, so many persons touch this chair." Meeting her on the street one day, he extended his hand; with profuse apologies, she declined to shake his hand, on the score of contamination. When these impulses overpower the individual, the line has been crossed, and he is insane; but this line is very difficult to draw. Dr. Wood told the man who could not touch the outside of his coat for fear of contamination, that if he were in his place, he would get on the wildest horse he could find, and he was quite sure that when the horse commenced to rear and kick he would grab hold of him, no matter how dirty the horse might be. The remedy was not tried.

Hallucination is expressive of a thing that is not true connected with the special senses.

Delusion of the same with the *intellect.*

Dr. W. knew a lady who, coming out of her room in the dim light, saw in the doorway the dim outlines of a monk, with gown and cowl. Turning up the light this figure became more distinct, and two, three, four, and finally a large group of monks appeared. She realized that these figures were subjective and not objective, that they were not produced by objects striking on the retina, but were *from* a disordered retina, or a centre back of it, just as we can produce flashes of light by pressing on the eyes. This woman was sane, because she realized the illusion; if she had believed in the illusion, and had been unable to correct it by the aid of sight, or hearing (by reason), she would have been insane.

A delusion is a fixed false belief, which arises and gradually overpowers one. One may have a fixed idea, and if not open to reason on it, he is insane. He related the story of a man who had the idea that his wife was unfaithful to him. He came to Dr. Wood to talk over the subject; he could give no valid reason for his suspicion, and said to the doctor, "Either my wife is not true, or I am crazy." After hearing his evidence (which amounted to nothing), and noting the fixedness of his idea, Dr. Wood told him that he was certainly insane. Some days this man would realize his delusion, while on other days he would be fixed in his idea. An important point made by Dr. Wood *is that a delusion does not necessarily have to be false.* Thus a man recently hung in this city for murder, had the idea that his keepers were persecuting him for religious reasons, and he killed one of them. In this case there was a foundation for the delusion; it was not entirely *false.* If a man believes that a building is at a certain spot, and if he believes this so that he cannot be changed in this idea, if he is not open to argument, he is insane, even though the building may be so located.

Delusions may be divided into *systematized* and *unsystematized*. In the latter class a man does not reason about his delusion, he merely asserts it. In the former he correlates his delusion with other surroundings and mental actions. In the latter a man may say that a gold watch is made of cheese, merely assert it. In the former he may reason that both the gold and the cheese are yellow, they both shine, they are both hard (when the cheese is old), etc., etc. In the case of the man who was hung (referred to above) there was a systematized delusion; he imagined that certain persons wanted to kill him, for reasons that were satisfactory to him. These two classes are usually well divided, but they occasionally run into one another.

PENNSYLVANIA HOSPITAL.

Service of Dr. J. H. Hutchinson.

Hydrocephalus.

I want to show you, gentlemen, this child with a hydrocephalic head. His parents present a good family history, his mother having had five other children. It is to be noted that each of the children had convulsions during the teething period, which is a somewhat interesting and significant fact, as tending to show a disposition towards cerebral disorder in these children; and it is especially to be noted that this particular child in question had more numerous and more serious convulsions than the rest, having as many as ten or twelve in twenty-four hours. After two months of these convulsions, along with a feverish condition, the head commenced to enlarge. After a duration of ten months, the convulsions diminished in severity. The child's functions are all normal, he is a good sleeper, though restless by day. He seems, however, to be somewhat deaf and blind, though to all appearances he was perfectly well up to the date of the first convulsion. When this child was born, the labor was more difficult than with the others. While hydrocephalus is most common among children, it may occur at any period of life, of which fact the case of Dean Swift is a striking example. About all we can do for these cases is to keep up the strength. I do not believe in puncture or compression, though of the two I believe the former to be more scientific. Compression is liable to increase the convulsions.

Patent Foramen Ovale.

I have here a most interesting pathological specimen, from the case of heart disease that was before you some time since (see page 720, Dec. 19, 1885). Owing to a disturbance in the ward, the patient became much excited, was found cyanotic, and died in a few minutes. You may remember, when the girl was before you, I stated that one of the possibilities in the case might be a patent foramen ovale, and the autopsy discloses this to be the fact. The heart is enlarged, the mitral orifice enlarged, but no cause apparently for regurgitation. There is a communication between the aorta and pulmonary artery, a little rough at the entrance of the pulmonary artery, which would account for the thrill felt in the third left interspace. I do not, however, find sufficient lesions to account for the irregularity and rapidity of the heart's action, so that I think there must have been a neurosis to account for these conditions. The fact that the disease dated from very early life, as I told you, would give us reason to suspect this condition of patent foramen ovale.

Pathological Specimens.

I have some specimens from a case of mania-a-potu, from a man who was brought into the house in a dying condition, and from whom we could not derive much history. There were diarrhœa and dyspnœa, and signs of pulmonary congestion, with marked distention of the superficial veins of the abdomen. When we look at the specimens, we find an enormous fatty liver, with a patch of congested lung and evidences of a recent pleurisy; the heart is flabby, and there is parenchymatous inflammation of the kidneys. The liver weighs 9 pounds. It is worthy of note that during life the symptoms made us entertain a slight suspicion of typhoid fever, and here we find some congestion of Peyer's patches.

Hepatic Catarrh.

This woman had typhoid fever, followed by a relapse, after which jaundice was ushered in by a chill and a great fall in temperature. A few days before the appearance of the jaundice there was an effusion of blood in the gluteal muscles, which went on to suppuration, and it was supposed, when the chill came, that she was suffering from sepsis, but it proved to be hepatic catarrh. The woman has been very ill, and it was supposed that she would die, but she has steadily improved.

Emphysema.

This woman, aged 44, has had eleven children, and was always more or less sickly, though her family history is good. After marriage she improved in health. Four

years ago she had bronchitis, with cough, and dyspnœa, which has continued, with intervals of comfort, until the present time. The chest is barrel-shaped, as we are accustomed to see it in emphysema; as you notice, there is very little expansion of the chest on inspiration, but it is elevated, and there is a depression of the supra-sternal spaces. The respiratory muscles are hypertrophied and resonance is increased all over the chest. The urine contains albumen and hyaline and granular casts, and the specific gravity is 1015. The hands are slightly cyanosed. We have here emphysema due to prolonged bronchitis. In such a case the patient must be kept in bed, as walking about will aggravate all the symptoms, because the aerating surface of the lungs is much diminished. This long-continued inflammation will have a tendency here, as elsewhere, to produce degeneration, and inspiration is impeded by plugs of mucus in the bronchi, which causes dilatation and rupture of the other parts. Here then we have lesions of the heart, lungs, and kidneys. The bronchitis is the most urgent condition, and calls first for treatment. This will consist of counter-irritation and muriate of ammonia, after which we will order iodide of potassium, which has been empirically recommended in emphysema, because it has been found to do good. The kidneys have not produced conditions calling for special medication. We will keep the patient quietly in bed, and nourish her.

Medical Societies.

CINCINNATI ACADEMY OF MEDICINE.

At the request of Dr. Taylor, Dr. Milliken reported a case which Dr. Taylor had seen in consultation with him. It was an interesting case of

Hystero-Catalepsy.

The patient, a stoutly-built young woman æt. 22, contracted, about the time of her marriage, symptoms of hysteria. She became pregnant, bore a son, who, with the doctor's permission, was circumcised on the eighth day. On the tenth day the child was dead from tetanus. Whether it was the result of the circumcision or not, the doctor was unprepared to say. The woman having no child to suckle, was soon again pregnant. After the birth of this second child, her attacks of hysteria became more cataleptic in character, and were aggravated by the sympathizing attentions of her devoted husband and friends. On one occasion she was left entirely alone in the room and watched unobserved. The catalepsy continued for quite a while. On one occasion her husband, wishing to do something, drew a sponge of cold water over her face and brought her to. This was then the routine treatment. Next she amused herself by being unable to pass her water, and it became the duty of the attending physician to visit her twice daily, and draw off her water. Dr. Taylor being asked to see the case, found no disease of the pelvic organs, but noticed a seeming redundancy of the mucous membrane about the orificium urethræ. Dr. Taylor suggested that principally for its moral effect this be snipped off. The patient then gave one of her best exhibitions of hystero-epilepsy for Dr. Taylor's especial benefit.

The reporter, a short time after, made the operation suggested, and snipped off all he could pinch up. This was followed by a marked improvement. She was able to urinate, and the attacks were less frequent and severe. Later, however, she found it necessary to "titillate" the region about the urethra for some half hour before being able to pass her urine. This is a case in which the attending physician is able to do very little good. What is done is easiest done by some physician in another city.

Dr. John A. Murphy thought that this woman's trouble started from a great revolution in her life, viz., sexual intercourse. It was increased by another revolution, viz., child-birth. He reported

A CASE OF DEATH FROM ATTEMPTED COITION,

which occurred in the practice of Dr. A. S. Dandridge, of this city. A newly-married couple had come to the city on their wedding tour and repaired to their room in a hotel. At the first approach of the husband the wife swooned away. Not recovering, the physician was called, who found her in a dying condition, and she lived but a few moments after his arrival. The husband stated that she had always been a healthy woman. The nervous strain, however, was too much for her. The doctor went farther to report another

CASE OF A NEWLY-MARRIED PAIR,

who were married in this city and went to Louisville, repaired to a hotel, and on the husband's attempt to consummate the marriage rite, the wife went off into a fit, in which she took the position of opisthotonos,

and which, from the description, must have been of the nature of an epileptic or hystero-epileptic fit. The husband bundled her up and brought her home to her parents. She continues to live with them, and although he has been married to her for some time, yet he has never had connection with her. She receives him as a friend at her parents' house, but at the first attempt at a caress on his part she goes off into one of her fits.

He then reported a case of

Hysterical Dyspnœa,

and said that in all these cases you would find an inherited fault of the nervous system. Some ancestor had gone insane, or had suffered some nervous trouble.

Discussion on Stretching the Sciatic Nerve.

(*See page* 38.)

Dr. Zenner was of the opinion that nerve stretching for the relief of pain has been successful enough to warrant its general use. It has, however, been used for numerous troubles, for the relief of which it is not calculated. Langenbeck once used it extensively for locomotor ataxy, but has since discarded it in that affection. He then discussed Billroth's method of nerve-stretching without operating. That is, in the case of the sciatic, in flexing the leg and thigh upon the abdomen as far as possible. Thirteen cases of treatment of locomotor ataxy have been reported, treated by extension of the cord by means of hanging with the hands.

Dr. Ramschoff mentioned a case in which he had stretched the tibial nerve for tetanus a number of years ago. This was followed by recovery. About three years ago he again practiced nerve-stretching for tetanus, and the convulsions remained absent only three or four hours and then returned. This absence was probably due to chloroform. Were I to have a case of tetanus now, I would stretch the nerve; if that failed, I would amputate.

Dr. Johnson, of Danville, Ky., who was present, said he had stretched nerves on five different occasions, two for acute traumatic tetanus, two for chronic tetanus; the other was for ordinary sciatica. As to the exertion of force, if a man stands flat-footed he can exert about 100 pounds of force. By bracing himself, he can exert much more. One should not brace himself. While some nerves from disease may be rendered weaker, others are made stronger.

Dr. Carpenter, of Stanford, Ky., was also present, and related three cases of nerve-stretching. One, the sciatic, had been followed by apparent atrophy. The limb was drawn up, and the patient, a female, walked with crutches, apparently a confirmed invalid. She had entered suit against him for $10,000 damages. Dr. Dawson, of Cincinnati, had seen the case in consultation, and pronounced the contraction hysterical and the atrophy due to non-usage.

Dr. M'Mechan then closed the discussion, saying that had he the operation to repeat, he would make the incision lower down, and pull the nerve suddenly downwards for five minutes, then upwards for an equal period.

MISSISSIPPI VALLEY MEDICAL SOCIETY.

Discussion on "Fracture of the Skull."

(*See page* 103.)

Dr. Wm. Byrd spoke concerning trephining. He advised that it be used early in cases where the bone was sticking down into the brain. Do not let it start up inflammation. He has had very good results with the trephine. The last ten years have changed considerably and materially the surgery of the brain and skull.

Dr. Louis Bauer, St. Louis: "Fracture of the skull is simply reduced to this question, Is there any pressure of the brain which is mechanically removable? Gentlemen, we hung a man in St. Louis four years ago; we exhumed the body, and on examination found the head smaller than his age and development would warrant. We found the brain asymmetrical, flattened on one side. We found premature ossification of the bones of the skull. The man was evidently in a state of semi-idiocy—irresponsible. He killed a man with a big stone, and no provocation. I am satisfied that through his hanging a judicial murder was committed."

He reported the case of an epileptic, very sullen, with other symptoms:

"Found microcephalon. Trephining was decided upon. We took out two buttons and the intermediate ridge. He improved wonderfully, recovering completely his mental and physical health. We have a new *rôle* for the use of the trephine. I would not hesitate one instant to remove everything which interferes with the movement of the brain."

He discussed trephining for osteo-myelitis. "What is more reasonable or more rational than to make a hole into the bone and let it out?"

Dr. A. W. Brayton, of Indianapolis: "Dr. Bauer has reported cases which should have come before a jury of medical experts." The doctor reported cases from Indiana where

judicial murder had been committed by a jury of farmers.

Dr. Joseph Eastman, of Indianapolis, said: "How many children receive an injury in early life and later become epileptics, insane, idiotic, and reach the asylum, and, possibly, the scaffold! We must carefully consider these injuries, and not trust too much to conservative surgery. We should consider well, shall we be conservative or heroic?

Dr. Charles Knapp, of Evansville, reported a case which occurred in his city. The patient fell from a bridge, a great height and with great force. It was a case of much interest, on account of the force taken to fracture the skull. It was found necessary to operate. He thinks that if there were symptoms of compression we should cut down. The patient made a good recovery, except paresis of the limbs.

Dr. H. H. Clark, of Danville, Ills., asked if there was any change in the temper of the boy. Dr. Brose replied that he had observed none. Dr. C. advised that the boy be carefully watched for several years.

Dr. Brose, in closing, said he hoped some one would take up the subject of cerebral localization. He explained that there was danger of depression of the parietal bone on pressure in the case which he presented.

CHICAGO MEDICAL SOCIETY.

Official Report.

Stated meeting, December 7, 1885.

The President, C. T. Parkes, M. D., in the chair.

Pneumonic Abscess

was the title of a lengthy and instructive paper by Dr. Edward F. Wells, of Minster, Ohio. He incorporated in his paper the histories of a number of cases which recovered under expectant and medicinal treatment. In an experience with 413 cases of pneumonia, abscesses occurred nine times. In closing his paper, the author said that he had arrived at the following conclusions:

1. The issue of pneumonic fever in abscess is rare, but this rarity has been greatly overestimated.

2. These abscesses vary much in size, and are most frequently found at the base of the lung.

3. They may in some instances, after pneumonia, be caused by excessive jarring or other motion.

4. They are usually formed rapidly.

5. In some rare instances the purulent contents may degenerate into a cheesy mass, to again soften, liquefy, and be discharged.

6. The symptoms and signs are quite distinctive, and sufficient for an accurate diagnosis.

7. The majority of cases recover, but in a certain proportion a cure is impossible.

8. Expectant and medicinal treatment, thus far, has given the best results, and the majority of cases should be managed upon this plan; but, under certain conditions, the most radical measures for relief are not only justifiable, but imperatively demanded.

Dr. Christian Fenger said that an interesting point in the paper is that the author takes the ground of the clinical and, perhaps, conservative man. Dr. Wells claims that we should not operate on the small abscesses, but only on large ones, as the latter are the more dangerous. Dr. Fenger believed that we should operate on all of them when indicated. Buhl, in Christiania, has operated on nineteen cases in which there were cavities. Up to the present time, we have reports of about thirty cases in which operations have been performed, but only seven of these cases have been such as reported by Dr. Wells, or abscesses incident to pneumonia. Since there have been only seven cases of abscesses of the lungs, incident to pneumonia, it stands to reason that these cases were severe ones, and that the abscesses were large. Dr. Fenger did not believe there had been much operating on small abscesses as yet; however, he would advocate it in case these abscesses were accompanied by a fetid bronchitis. There is an abscess-cavity, which Rokitansky calls a chronic abscess, in which there is not connective tissue enough to allow the cavity to close. This cavity is a source of danger to the patient, as sometimes, for one reason or other, septic micrococci gain entrance, acute inflammation or gangrene follows, and the patient dies. In such a condition, we should try to obliterate the cavity. Operative treatment of these abscesses has been so infrequent that we cannot say that it possesses any advantage over medical treatment. The important point to be decided in the future is how to get an understanding of where the danger-line is; how long we can afford to wait, and how much strength can we afford to let the patient lose before we operate? It is, perhaps, well to put in a word of warning against operating too early, as we are all aware that patients who recover without an operation do better than those on whom there have been operations. Dr. Fenger said that in case a cavity gives rise to fetid breath, frequently a fetid bronchitis is developed,

and subsequently an inter-lobular pneumonia in the other lung, or in the upper part of the lung in which the abscess exists. Relative to Dr. Wells's remark that he never suppresses the cough, Dr. Fenger stated that it is a fact that the cough ceases almost instantly after the abscess is opened.

Dr. R. Tilley said that he could not see of what benefit inhalations of turpentine could be in such cases, as the abscesses are analogous to those which occur in the more external portions of the body, and we never expect to benefit them by using turpentine. He would expect better results from administering this medicine internally, as he had recently read that the German physicians are using turpentine very successfully, by giving it internally, in diphtheria.

Dr. Wells, in closing the discussion, said that he wished to recall the attention of those present to the important point that these abscesses occur most frequently in the lower lobe of the lung, similarly to pneumonia. The principal object of his paper was to do what he can to counteract the tendency among the medical journals to advise early operation in pulmonary abscesses. He thought the statistics so far do not prove the operative treatment to be superior to the expectant and medicinal treatment, and he thought surgeons were too prone to take the cases into their own hands, and that they do not leave enough to the *vis medicatrix naturæ*.

A Case of Expulsion of a Large Sub-mucous Fibrous Tumor of the Uterus, per Vias Naturales, or Colpo-Myomotomy,

was the title of a paper read by Dr. J. H. Etheridge. Mrs. A. B., aged forty-three years, married twenty-eight years, mother of three children, suffered from menorrhagia for six years past. She has had frightful hemorrhages, but otherwise she has been healthy. In 1882, the first examination which he was permitted to make disclosed a large sub-mucous, fibrous, uterine tumor, at the top of the fundus uteri, extending one inch above the umbilicus, its lateral diameter equalling its longitudinal diameter. A uterine sound was introduced eleven inches. There was no rectal nor vesical disturbance. The only inconveniences experienced were the hemorrhages and a "high stomach." The hemorrhages have repeatedly brought her to death's door, but her recuperative powers were astonishing. Dr. Etheridge then detailed her history for two years, during which time she had had several hemorrhages, which were controlled by sponge-tents, rest, and ergot. He detailed also the treatment by a homœopathic physician, which had consisted of incisions into the cervix uteri, and the administration of sulphuric acid and fluid extract of hydrastis canadensis, the latter remedy being extolled as a sure cure for uterine fibroids. On November 12, 1884, Dr. Etheridge was called to see the patient, whom he found in a pitiable condition. She was exsanguinated, feverish, and dyspeptic. She was placed on tonic treatment and rapidly convalesced. In October, 1885, she had another hemorrhage, which lasted twenty-four hours, before a sponge-tent was introduced. This tent was speedily forced out. Three more sponge-tents were subsequently introduced, and an enema of thirty drops of fluid extract of ergot was given. Powerful uterine contractions ensued; the capsule of the tumor was ruptured, and the hemorrhage ceased. Three days after that, one pound of the tumor was pulled and cut away. The tumor was pultaceous, friable, and accompanied by a disgusting odor. On the day following, one-half of a pound of the tumor was taken away, and two days later as much more. Three days later the patient was put under the influence of ether, and Dr. Etheridge attempted to remove the remainder of the tumor, but only succeeded in removing two pounds more. After this operation, the patient went into collapse, and nearly died. However, she recuperated so rapidly that in five days thereafter he removed another pound of the tumor. Five days later he succeeded in getting away another pound and the pedicle. The uterus, during the ten days past, had decreased rapidly in size, and the fœtid vaginal discharge had lessened. During the three weeks in which the six pounds of gangrenous mass were removed, he expected the patient would develop sepsis, but none occurred. As the patient was continually under the influence of ergot, and shreds of the tumor came away between the times of the operations, it is safe to estimate the weight of the tumor at thirteen pounds. The points of interest in the case were that the hemorrhages recurred most severely in the autumn, which was probably due to the changes in the circulation incident to the occurrence of cold weather; and also that, in order to remove these tumors expeditiously, it is imperative that we should be enabled to draw the tumor down into the vagina, where it can be grasped, and, at the same time, to continuously contract the uterus behind the descending tumor, so as to facilitate traction and to avoid hemorrhage.

The President remarked that this case teaches the lesson of the importance of early interference in fibrous tumors of the uterus, especially those that are large and accompanied by hemorrhages, which facts indicate that they are close to the mucous membrane, and under the effect of the contraction of the muscular fibres of the uterus, and thus susceptible to the influence of ergot.

Dr. Jacob Franks then detailed

A Case of Vesical Calculus,

in which lithotrity was attempted. A Bigelow lithotrite was introduced, which grasped a stone measuring two inches. Upon turning the screw the instrument broke, and in consequence of this accident a portion of the instrument was left in the bladder. On the next day the lateral operation of lithotomy was performed, and the calculus and the broken piece of the instrument removed. The patient made a good recovery.

The Society then adjourned.

Editorial Department.

Periscope.

Lymphadenosis.

Dr. H. A. Bunker read notes of a case before the Brooklyn Pathological Society which, he remarked, was, perhaps, of special interest on account of the rapid course of the disease.

The patient, a maiden lady aged sixty, had been under his care for about three years, being the subject of chronic gastric catarrh, suffering during rather frequent exacerbations from severe attacks of palpitation of the heart, a sense of impending death, etc. She had had no trouble attributable to the menopause, which, she assured him, had occurred normally, and during his acquaintance with her she had never presented any symptoms pointing to uterine disturbance. She had recovered so far from her anæmic and debilitated condition, resulting from her gastric trouble, that for several months previous to her last illness he had not been called upon to prescribe for her. In June, 1885, she consulted him for œdema of the eyelids and slight swelling of the feet, complaining, also, of great weakness. Examination of the urine giving a negative result, a physical investigation showed an enlargement in each upper eyelid, hard and painless upon pressure, together with enlarged submaxillary, axillary, cervical, and inguinal glands. Later on, an examination at her own home revealed what he, at that time, took to be a mass of enlarged mesenteric glands, but which the autopsy showed to be the specimen presented. He was unable to detect any change in the liver or the spleen, but perhaps this would have been difficult if they had been involved, on account of the enormous tympanitic distension of the abdomen. The heart and lungs presented no abnormality of action. The only subjective symptoms were loss of appetite and gradually-increasing general weakness, besides the distress occasioned by the tympanites. On August 10, the patient had an attack of dyspnœa followed by great prostration. Subsequent attacks occurred in rapid succession until September 5, when the patient died of asthenia and asphyxia.

From the appearance of the dyspnœa, due, as he believed then and as was shown at the autopsy, to the encroachments of the enlarging bronchial glands, the failure of the patient was rapid. The temperature, which had previously remained about stationary at 100° F., rose to 103° and 104°, and so continued to the end. The pulse, which had been from 80 to 84, now rarely fell below 100, and during the attacks of dyspnœa would rise to 120, 130, and 140 to the minute. During the early part of this distressing period Dr. W. H. Bennett was called in consultation and confirmed the diagnosis of lymphadenosis.

Arterial Ligation as a Prophylactic Measure After Sudden, Complete, and Permanent Occlusion of the Chief Vein at the Root of an Extremity.

Dr. Lewis S. Pilcher thus concludes an article in the *N. Y. Med. Jour.*, January 9:

The final conclusions reached as the result of the foregoing discussion may finally be profitably stated in the following:

1. Serious circulatory and nutritive disturbances are to be apprehended.

a. In the upper extremity, when, in addition to the occlusion of the main vein at its root, simultaneous occlusion of any consid-

erable number of the lesser and collateral branches has also taken place.

b. In the lower extremity, when the occlusion of the main vein at its root is sudden and complete, and has not been preceded by any conditions which might have occasioned a previous dilatation of collateral channels or the development of new ones.

2. The accidents of excessive œdema and of gangrene, when they occur, are due to the intense and active congestion of the limb through the arteries with blood for which there is no adequate outlet.

3. The development of collateral paths is not by the breaking down of valve-barriers at the entrance of large collateral trunks, but by the dilatation of a multitude of minute branchlets. To effect this, an increased arterial *vis a tergo* is not required. Any increase in the normal blood-pressure is attended with danger of overwhelming and fatally choking up the somewhat slowly enlarging collateral radicles.

4. The diminution of the amount of arterial blood which enters a limb whose chief venous outlets have become occluded, down to an amount not greatly in excess of that which can readily find an outlet from it through paths still remaining, is the first great indication to be fulfilled in the treatment.

5. Whatever method is adopted to restrain the flooding of a limb with arterial blood, it must still permit the entrance of a supply sufficient for the nutrition of the limb. For this reason, in the lower limb, ligation of the common femoral is to be avoided, especially in the light of the disastrous results of such ligations already recorded.

6. Ligation of the axillary artery in the upper extremity and of the superficial femoral in the lower are safe expedients, and to be adopted as prophylactic measures, whenever occlusion of the venous outlets of a limb is so great as to hazard the integrity of the limb by reason of the circulatory stasis produced.

The Treatment of Habitual Constipation.

Dr. Alfred S. Gubb thus concludes an article in the *Med. Press.* November 11 :

The mildness of the effect of Friedrichshall water in these cases is, according to my own observations, well marked. In no case, even after prolonged use, did it prove in any way excessive, and when its use is abandoned for a time, the constipation only recurs gradually when its regulating action on the intestines has given place to the habit of the body or errors in diet which produced the tendency to constipation in the first instance. The non-occurrence of the reactionary constipation which so generally follows the habitual use of aperients, is doubtless to be attributed to the large quantity of chlorides present in Friedrichshall water, and to their favorable influence on the progress of digestion and diffusion. In short, the class of cases in which I have found this water of especial service, comprises hemorrhoids accompanied by habitual constipation, hepatic congestion, and in the constipation of pregnancy, which is so often complicated by derangements of the digestion, headache, and dyspnœa. There are many cases of cardiac disease and of cardiac irritability in young people in which it is very serviceable in continuous and diminishing doses. It has long had a high reputation in the treatment of gravel, and for the prophylactic treatment of renal calculi, but of this I am unable to speak from experience. It has appeared to produce a favorable impression in the numerous cases of strumous and glandular swellings, where we have to contend with a sluggishness of the bowels and of tissue-change generally. Here Friedrichshall water acts as a stimulant as well as an aperient. A certain diuretic effect which is manifested, is not uncommonly of service in cases where it is desired to increase the proportion of watery constituents of the urine. It is less adapted to cases of renal disease where our object is to produce copious watery evacuations of a drastic nature, but to lessen venous congestion by gentle and continuous means, Friedrichshall water is peculiarly indicated, and is perhaps without a rival.

Recovery from Malignant Pustule.

Dr. W. E. Buck records this case (*Brit. Med. Jour.*):

Mr. F——, aged thirty-one, a veterinary surgeon, experienced on October 6 a stinging sensation at the back of the right wrist. A small bleb was formed, which he scratched off, and there was some tenderness of the elbow and armpit. He had a slight rigor. On October 8 he was seen by Dr. Meadows, who prescribed some salicylate of soda and tincture of aconite, in frequent doses, as his temperature was 104°, and the rigors continued almost the whole of the day. A black eschar began to form on the afternoon of the 8th, and on the 9th it became about the size of a sixpence; its base was red and œdematous, and surrounded by some vesi-

cles in a circular shape. The temperature was nearly 104°; the patient felt cold, and the tongue was foul. I visited the case with Dr. Meadows, and we injected pure carbolic acid under the eschar, using an ordinary hypodermic syringe. Unfortunately, we could only introduce a small quantity, as it oozed out in the withdrawal of the syringe, and with it a serous-looking fluid. I dried some of this fluid on a cover-glass, stained it with methyl-violet, and found the well-known bacilli of anthrax. We prescribed large and frequent doses of soda-hyposulphite, and ordered, also, a large quantity of meat. Under this treatment he rapidly improved. On October 12 we again injected carbolic acid. The temperature came down, and, as the patient said he felt all right, the hyposulphite of soda was reduced to three times a day. The eschar did not finally separate for nearly six weeks, and the ulcer then soon healed. I believe that the main remedy in this case was the injection of pure carbolic acid, a mode of treatment which does not seem very painful. There was a clear history of the disease, which was contracted exactly twelve days before its first appearance, Mr. F—— having examined the flesh of an animal that had died from anthrax.

Case of Hermaphrodite.

Dr. W. John Lawrie describes this case in the *Glasgow Med. Jour.*, November:

On October 6, Mrs. Q., in Ayr, gave birth to a child at the full term, which presented the following peculiarities: The labia majora appear to be somewhat prominent and distended, giving the impression of hollowness to the examining finger. At their lower extremities there is a minute opening, forming evidently the orifice of vagina and urethra. The margins appear red, moist, and somewhat inflamed, as if from the passage of urine over their surface. On questioning the nurse, she cannot affirm that urine does proceed from this opening, but in the absence of other outlet, it must be assumed to be the passage for the urinary secretion.

It is at the upper extremity of the labia that the unusual feature of the case is found. Here is situated a small but well formed penis, 1½ cm. in length. The glans penis is of normal appearance, except that it is unprovided with a meatus. The foreskin is perfect in development, and though capable of covering the glans, remains normally in a drawn-back position. The frænum consists of a tightened band of tissue, arising at the point of the glans as in normal conditions, and extending downwards and backwards till it disappears in the orifice of the vagina. Labia minora are not present.

In regard to sex, the child appears to approximate more nearly to the female than to the male organization, as there are no testicles, and the vagina, though small, has the normal situation. The vulva, however, is unusually prominent, resembling somewhat a scrotum divided by a median section. It has already been observed that there is no meatus urinarius. Otherwise the child appears to be of normal constitution, and is healthy and well nourished.

Eruptions Due to the Use of Certain Medicines.

We take the following from the *College and Clinical Record:*

Quinine—Erythema scarlatina; papular erythema (Kohner). Hemorrhages and purpura. Pemphigus, œdema, and prurigo.

Cinchona, belladonna, stramonium, strychnine, have the same characters as quinine.

Digitalis—Erythema after long use (Traube).

Aconite—Vesicular exanthemata.

Santonine—Pemphigus, vesicles (Deschamps).

Opium and Morphine—Erythema (Apolan); papular eruption with marked desquamation and itching.

Pilocarpine—Increased perspiration.

Atropia—Diminished perspiration.

Phosphorus—Purpura.

Mercury (internally)—Erythema (Kalus, Zaissi, Gamberini); eczema (Aley, Fournier, Gamberini).

Arsenic—Erythema and papules (Imberts-Goubayre); vesicles and pustules (Bazin, Raymondi, Gamberini).

Carbolic Acid—Erythema (Taourschi); pemphigus (Zaissi).

Salicylic Acid—Purpura (Freudenburg); vesicular angina, pemphigus.

Chloral—Erythema slightly colored, itching, desquamation, purpura and petechia (Crichton and Brown); eczema (Kirn).

Copaiba, Cubebs, Turpentine—Pemphigus, erythema, eczema (Renter).

Cod-Liver Oil—Acne.

Iodide of Potassium—Papules, vesicles (Bumstead, Gamberini); pustules, ecthyma, eczema (Landrieux); ecchymoses and purpura (Tilbury Fox).

Bromide of Potash—Papules and pustules, deep tubercles with ecchymoses, pemphigus, ulcers.

Hemorrhage from the Rupture of the Sac of a Spina Bifida, Resembling Symptoms of Placenta Prævia.

In the *Am. Lancet*, Dr. Tye reported the case of a woman to whom he was called recently, and found in labor. Pains were coming regularly, and with each contraction of the uterus there was quite a profuse gush of blood. The accouchement had commenced with the escape of a very large quantity of water, which was immediately followed by the loss of a considerable amount of blood. The os was not sufficiently dilated to make a diagnosis positive at once, but the doctor thought he had a case of placenta prævia. As the labor progressed and os dilated, an acephalous monster was diagnosed.

The fœtus, on being expelled, was found, besides being acephalous and having rudimentary genital organs, to have a large spina bifida extending from the neck to the sacrum, the sac being ruptured. To the spinal opening large clots of blood were attached, and over the interior the sac small clots adhered. The placenta came away in half an hour with a very moderate amount of hemorrhage. The child was ensanguine, but the mother showed no symptoms of loss of blood.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a 12mo volume of 62 pages, Dr. G. H. Rohe, of Baltimore, discusses various common cutaneous diseases, and their treatment. His work is entitled "Practical Notes on the Treatment of Skin Diseases," and may be had by remitting 25 cents to the author.

——A lecture on "Tumors," by Dr. N. Senn, of Milwaukee, Wis., has been reprinted in neat form, and will be found to be an interesting survey of the subject.

——Dr. Charles N. Oliver, of this city, has devised a new series of metric test letters for determining the acuity of direct vision for form. They have several advantages not possessed by any other single form of test-card. They are prepared by J. W. Queen & Co., Philadelphia.

——In a reprint before us, two rare cases of abdominal injury are described by Dr. J. A. Stucky, of Lexington, Ky.

——With the beginning of the year, the *American Practitioner* and the *Louisville Medical News* were consolidated in a bi-weekly under the name of the *American Practitioner and News.*

BOOK NOTICES.

Practical Suggestions Respecting the Varieties of Electric Currents and the Uses of Electricity in Medicine, with Hints Relating to the Selection and Care of Electrical Apparatus. By Ambrose L. Ranney, M. D., etc. 8vo., pp. 148. Illustrated. D. Appleton & Co., New York.

The nature of this little volume is so fully set forth in the title, which we have given at length, that there is no need of further explanation. The author is a popular teacher on the branch, and his book is a summary of the lectures which he delivers to his classes. It is clearly written, quite practical in tone, and offers an excellent epitome of the subject.

The Field and Limitation of the Operative Surgery of the Human Brain. By John B. Roberts, M. D., etc. 8vo., pp. 80. Illustrated. P. Blakiston Son & Co., Phila.

The contents of this monograph are grouped under three headings, treating respectively of the Principles of Cerebral Surgery, of Cerebral Localization, and of the Operative Treatment of Cerebral Lesions. These topics are discussed with that careful research and close reasoning which are the characteristics of the author, and which place the difficult and obscure branch of surgery which he has undertaken to investigate in as clear a light as the extent of our present knowledge allows.

Transactions of the Indiana State Medical Society for 1885. Cloth. 8vo., pp. 307. Indianapolis, 1885.

This volume contains some thirty different articles, most of them original contributions to medical science, discussing matters of general interest. The address of the President, Dr. J. H. Woodburn, is upon the actual advances in medical practice, and the hopeful view he advocates is supported by much later on in the volume. Several of the articles are on the local disease and medical history of the State, and will have permanent interest to the medical historian. Indeed, the volume proves throughout that the Indiana State Medical Society is an active and thriving organization.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE MICRO-ORGANISMS OF SYPHILIS.

If the theory of bacteria as pathogenic elements would seemingly apply with justice to any disease, it should be syphilis, for, like in tuberculosis, we have here a virus which may be inherited, or which may be latent in the organism for a long period, and which may apparently disappear from the system for a greater or shorter time, only to break out again with renewed force. Something similar also occurs in relapsing fever, only that here the period during which the microbes are inactive and latent in the organism is very short, lasting but one week. All authors now agree that in relapsing fever, as well as in anthrax, the existence of bacteria as pathogenic elements has been satisfactorily proved; so that we have at least the hope that the same will soon be said of syphilis, and if the recent reports can be relied upon, the discovery has at last been made.

Not long ago, Lustgarten found in the secretion of the hard chancre, in the indurated part of it, in the syphilitic suppurating bubo, in rupial ulcers, and in gummata, when they had selected as their seat internal organs, a peculiar bacillus, which while greatly resembling that of tuberculosis, behaved under pure culture in a manner sufficiently differing from that of the tubercle-bacillus, to be recognized as another separate and distinct species.

Soon after, the observation was made that the smegma præputiale contained bacilli evincing in every respect characteristics so similar to the syphilitic bacteria of Lustgarten, that the two could not be distinguished from each other. Alvarez, Tavel, and others carefully investigated this point, and they all agreed that the two kinds were really one and the same. As the precautions had been taken by the investigators to select smegma from persons undoubtedly free from the luëtic virus, and as the same bacilli were met with there, the fact seemed undeniable that Lustgarten's bacillus could not be the pathogenic micro-organism of syphilis.

The latest report comes from Leyden, well known for his painstaking in researches of this kind. With the aid of his assistants he made a thorough investigation of both species, and communicated the results of his labors in the meeting of the Berlin Med. Society, November 2, 1885, (*Deutsche Med. Zeit.*, Nov. 12, 1885.) He found, indeed, that both species behaved in nearly the same manner under various coloring processes; and that their size and shape also agreed. But what completely disproved their identity, was their different be-

havior under pure culture. The most important points concerning the smegma-bacilli are, that they become at once deprived of their color when placed into concentrated acid; that they remain uninjured for at least one minute in a solution containing one part acid and two parts water; and that in one part acid and four parts water they retain their power of development for fully ten minutes, all properties not possessed by Lustgarten's bacilli.

There is, therefore, a possibility that Lustgarten's bacillus may be after all the true germ of syphilis. The question can be definitely settled only by further investigations, and it will especially be necessary to inoculate animals or human beings with such bacilli obtained from pure culture, ere the point can be decided. Whether the discovery will ever have any result favorable to treatment is difficult to say; but in cases of doubtful diagnosis, the presence of the specific bacilli would at once determine the nature of the disease.

INFLUENCE OF METEOROLOGICAL CHANGES ON DISEASES OF THE RESPIRATORY ORGANS.

Especially in marshy localities, the influences which are exerted by atmospheric changes on certain diseases of the chest have long been observed, and the opinion has also been expressed at times that they obey definite laws; but either because there was not material enough on hand, or for other reasons, the subject has never been scientifically investigated.

In Maldorf, in Germany, the state-physician, Dr. Michaelsen, accumulated a large material. During 21 years, 3,378 cases of diseases of the respiratory organs were observed by him in connection with meteorological influences. Dr. Dose, who, after M.'s death, came into possession of these records, has carefully studied them, and discovered from them the following laws (*Deut. Med. Zeit.*, December 21, 1885):

Warm and humid air, west wind and rain, have the most favorable effect on the organs of the chest, but these are especially exposed to danger:

1. The lower the temperature.

2. The more, during the prevalence of a low temperature, the northeast and the north wind take the place of the west wind; while

3. During the warmer season of the year winds coming from the east do not unfavorably influence the respiratory organs.

Milder as well as graver forms of these maladies are subjected to these laws. Simple bronchial catarrh, catarrhal fever, gastric catarrhal fever, and catarrhal rheumatic fever and pneumonia, obey these laws, while whooping-cough is not affected by them. The influence of temperature is greater than that of the direction of the prevailing wind. This is the reason why the frequency with which these complaints occur during the winter months reaches its height in March and continues rather high until May, because low temperature and east wind both happen and act together. On account of the usually warmer weather during autumn, the dangerous influence of these causes is diminished.

These results are of great practical interest, as they directly concern climatic therapeutics. They teach, for instance, that it is best for consumptives to seek a climate equally free from extremes of temperature, and of the direction of the wind, as above indicated, and where the atmosphere contains the least possible amount of dust. We further learn from them, that while it is probably impossible to discover a climate exactly suited for persons with a tendency to diseases of the respiratory organs, the physician can advise such patients when it would be better for them to take active out-door exercise, and when they should be confined to their rooms, which ought to be kept at a higher temperature than that of the external atmosphere during the cooler seasons. These results, finally, also explain why patients suffering from lung-diseases or from chronic bronchial catarrh, often become suddenly worse without any apparent reason. At present, when meteorological changes are persistent almost to a certainty, the cautious physician can perhaps prevent exacerbation of the symptoms of these patients by a strict observance of the above laws.

THE SPEECH OF THE EYES.

Prof. Hugo Magnus recently delivered in Berlin a lecture on "The Speech of the Eyes" (*Deutsche Med. Zeit.*, November 12, 1885). First he showed how various thoughts and emotions may find their expression through the eyes, how rage, joy, sadness, sympathy, all may be indicated by one look, and how a question may be asked or be replied to simply by one scarcely observable movement of the eye. But the most interesting part of his lecture was a point with which many a physician may not be acquainted; not from ignorance, but simply because he has never given the subject any thought, viz., the fact that all the various expressions of which the

eye is capable, are not at all made by the eye itself, *i. e.*, by the eyeball, but by the movements of neighboring parts. The eye itself may be stationary, not the least motion may be observed in it, and yet the raising of the lids expresses our surprise, half-closing them together with contraction of the brow indicates our displeasure, and a peculiar fibrillar-like movement of the lids, the orbicularis palpebrarum, and the parts around the nose, together form what we are in the habit of calling "a merry twinkle." Many a one who will read these lines will at once acknowledge that such is the case, and that the facts are as stated, but at the same time he will acknowledge that he had never thought about it, and had never imagined that in all the manifold expressions which we ascribe to the eye—the mirror of the soul—the eye itself has no share. When a criminal has his character pictured in his eyes, it is not they that tell us the moral depravity of the man, but the play of the neighboring muscles, which, perhaps, for years, always obeying the impulse from the brain, form together the group we call physiognomy.

Notes and Comments.

Abdominal Gestation.

A case of this form of extra-uterine fœtation has recently occurred in the practice of Dr. T. Chambers, Lecturer on Midwifery at the Sydney University. It is reported in the *Australasian Medical Gazette*, the organ of the combined Australasian Branches of the British Medical Association. The patient, 38 years of age, underwent Emmet's operation and the operation for ruptured perineum within a fortnight, in December, 1884, having suffered injury during labor two years previously. She ceased to menstruate in February, 1885. In May she suffered from constant discomfort about the lower part of the abdomen, the uterus was found to be enlarged and high in the pelvis. Pregnancy was suspected. On June 10 she was seized with severe abdominal pain, with extreme collapse. The pain was intense along the line of the transverse colon. Scybala were cleared from the rectum, and the patient rallied. On June 17 a second attack occurred, followed by jaundice. A third seizure followed the disappearance of the jaundice a week later. Early in July, the cervix was dilated with tangle-tents. A swelling was detected, pressing the posterior wall of the uterus forward; this swelling could plainly be felt from the rectum. The swelling was aspirated, and several ounces of liquor amnii escaped. The patient's general condition became very unfavorable, and on July 18 abdominal section was performed. The uterus was found to be fixed posteriorly. After an omental adhesion was removed, and the operator's index finger introduced behind the organ, a great quantity of jet-black, intensely fetid fluid escaped from a swelling somewhat to the left, and more fluid of a similar character welled up from the sides of the pelvis. It appeared impossible to proceed further, so the cavity from which the black fluid issued was stuffed with antiseptic lint and two sponges. The patient rallied for a short time, but died eight hours after the operation. The ovaries and tubes were found to be intact; but behind and to the left of the uterus was a large cystic cavity, the walls of which adhered to Douglas's pouch, the ureters, and other soft tissues. The cavity was divided into two portions; the left and posterior part contained a fœtus, of about the thirtieth week, with detached placenta and decomposed blood-clots. The other part lay between the back of the uterus and the left compartment of the main cyst. It contained liquor amnii, and was lined with a smooth delicate membrane. The three attacks of pain and collapse probably represented repeated hemorrhage into the cyst, due to detachment of the placenta.

Rare Tumor of the Orbit.

The *New York Med. Jour.* tells us that Story (*Ophth. Rev.*) reports an interesting case of orbital tumor occurring in a young girl who had never suffered from any inflammation or painful affection of the eyes or orbits. As long as could be remembered there had been noticed a small lump beneath the left lower eyelid toward the nasal side. This lump became more prominent at certain times, and slightly discolored, and this was especially noticeable when she laughed or cried, or after stooping or taking violent exercise. On palpation, a hard body of about the size of a small pea could be felt beneath the discolored skin, and was freely movable in all directions in the orbital cavity. It could be drawn forward and made to project through the fornix beneath the eyeball. On dividing the skin and fascia over it, the tumor projected through the opening, inclosed in a thin, but firm capsule. On dividing this capsule, the tumor popped out upon the cheek, there being no pedicle. It was nearly spherical, being one centimetre

long and seven millimetres broad, and at one extremity of the longer diameter a smaller spherical tumor, about two millimetres in diameter, was firmly attached to the primary one. On making a section with a saw, the tumor was seen to be formed of a series of concentric lamellæ, the peripheral layer resembling bone in appearance. A microscopical examination, however, showed no bone, but only a series of different layers of fibrous tissue and calcified matter.

A New Test for Human Milk.

Dr. Hélot (*Lyon Medical*, October 18,) has discovered a method at once simple and practical to test the quality of woman's milk. While, of course, chemical analyses are reliable, yet they are so long and difficult that M. Tarnier has recommended physicians to accustom themselves to recognizing the richness of milk by the sight. Over this method, that of M. Hélot has the great advantage of precision. It consists of a comparison by means of a dropper of the number of drops in a volume of distilled water at 15°, with that in an equal volume of the milk. Good milk, that which will cause a gain of 25 gm. per day in the weight of the child, gives a proportion of 35 drops to 30 of distilled water. The number of drops may vary, increasing to 36, 37, or 38. The milk is then of superior quality. If, on the contrary, one gets only 33 drops, or less, he should mistrust the milk. The Pravaz' syringe allows of the accurate accomplishment of this examination; it only being necessary to remember the ratio of 5 to 6 between water and good milk. The test should be applied to each breast in the middle of the nursing.

Connection between Affections of the Eye and Spinal Curvature.

A Polish physician, Dr. Jasinski, has traced a connection between errors of refraction and curvatures of the spine. In thirty-seven cases of curvature he was able to prove with certainty the previous existence of these or other abnormal conditions in the eyes, such as insufficiency of the internal rectus, astigmatism, asthenopia, etc. Myopia alone, however, does not appear to cause curvature. Unequal vision and insufficiency of the internal recti seems to be most efficient in the production of spinal curvature. Spasm of the accommodation also is capable of producing it. Removal or relief of the eye affection is followed by improvement in the spinal curvature—a troublesome and obstinate class of cases in orthopædic practice.

The Treatment of Lienteric Diarrhœa in Children.

M. J. Simon (*Prog. Méd.*) orders the following powders in cases of rebellious lienteric diarrhœa in children five or six years old:

Powdered crabs' eyes	15	grains.
Sodium bicarbonate	8	"
Magnesia	30	"
Calumba	4½	"
Nux vomica	1½	"

Divide into twenty powders, one to be taken twice a day, before eating. If the child refuses to take the powders, he orders:

Tincture of cinchona, rhubarb, calumba, each	75	grains.
" nux vomica	8	"

Dose, five to ten drops, before each meal. In addition, the diet is to be regulated.

Ovariotomy in Madrid.

The Madrid journal *El Genio Medico-Quirúrgico* publishes in a tabular form the statistics of six cases of ovariotomy performed in Dr. Kispert's clinic in Madrid, from June, 1882, to October, 1885, all of which were successful. There was ascites in four cases, a multilocular cyst in four cases, and omental adhesions in three cases; while one case was a unilocular parovarian cyst, and one a dermoid cyst. After the operation metrorrhagia occurred in all cases; in three as early as the second day, and in one not until the ninth day.

Vaccination for Measles.

In connection with the recommendation of vaccination as a cure for whooping-cough, we note that Dr. A. O. Strout writes to the *Cincinnati Lancet and Clinic*, October 31, 1885, that three years ago they had several cases of small-pox in his vicinity, also an epidemic of measles at the same time. On account of the small-pox almost every one was being vaccinated, and he observed that all the children who were vaccinated about the time they were exposed to the measles had them so light that they were not confined to the bed at all, and this not in one case, but probably twenty. Let us hear from our readers about this.

Latent Pneumonia.

Dr. Frank Grauer concludes the report of a case in the *N. Y. Med. Jour.*, December 19, by making the following valuable suggestions:

1. That the tolerance of pneumonia is variable in different persons. Here was a man with organic disease of the heart and three lobes of his lungs completely solidified, who yet did not complain of dyspnœa or shortness of breath, showing that the two upper lobes were sufficient to do the work of respiration.

2. That we should never rely on the remarks of a patient, and direct our attention only to the part he thinks is affected, but examine every organ carefully and thoroughly, so as to do justice not only to ourselves, but to all who are interested in the case.

Chloride of Gold and Sodium in Pertussis.

Dr. G. L. Magruder, of Washington, D. C., reports in the *American Journal of Obstetrics* successful results from the use of "chloride of gold and sodium" in pertussis. His formula was:

R.	Auri et sodii chlorid.,	gr. ij.
	Aq. destil.,	℥j.

With directions to give five drops every two hours, beginning as soon as possible.

Special Report.

PROGRESS OF OTOLOGY.

BY LAURENCE TURNBULL, M. D.,

Of Philadelphia.

Aural Surgeon Jefferson Medical College Hospital, etc.

THE DEAF MUTE.

Most of my readers are aware that I have taken a lively interest in the relief and education of the deaf mute. I have written and printed at various times communications on the subject, and I have obtained action of the Philadelphia County Medical Society in advocating the articulate system of instruction.

In a recent paper read before the American Association for the Advancement of Science, Prol. Graham Bell made a startling assertion that there was one deaf mute to every 1500 of the world's inhabitants. This distinguished inventor and able writer holds to the doctrine that the marriage of deaf mutes produces deaf-mute children. This he endeavors to prove by statistics of deaf-mutes, forty-five per cent. of whom marry, and with each succeeding generation the tendency to the infirmity increases, and in one family he found ninety deaf mutes in four generations connected by blood or marriage. He and all thinking phpsicians must consider this an evil that should be prevented. First, by imparting this information to physicians and friends of the thirty-five thousand deaf mutes of the United States. Again, the number of institutions for the instruction of this class is too small, only numbering forty-eight, the first of which was founded at Hartford, Conn., in the year 1817; so that the great mass cannot be reached and are not available.

It is therefore advisable that branch departments should be instituted and have a separate room and teacher in our public schools; thus they would not be entirely separated from the influence of the family and communication with their fellows of the schools. At present the cost of instruction in our public institutions of the state is about two hundred and twenty dollars per pupil, but by educating them with the children of the public schools by means of a separate teacher the cost would be much reduced, as each teacher could instruct ten pupils, say at a salary of about eight hundred dollars; the cost of boarding the pupils would be thus saved. We also advise all pupils to be taught by the German method, namely articulation, as I feel satisfied from my experience that all bright deaf mutes can acquire articulation. In a conversation with Prof. Bell we stated the following as our opinion and the result of our experience in a number of deaf mute marriages which had come to our knowledge where both parents were absolutely deaf to all sounds, and were so from their birth. The children born to them were only in a few instances deaf mutes. When one or both parents could hear the human voice as sounds but were unable to distinguish words, the whole number of children born were hearing children. In those who could distinguish loud noises, such as clapping of hands, the ringing of bells, thunder, cannon firing, etc., a part of the children were born deaf.

To remedy the evil of deaf mutes marrying, Prof. Bell advocates the separating them as much as possible from each other during the time he or she is being educated. They should not be sent to asylums; they should be taught English instead of the sign language. Of 2,106 pupils in the Deaf Mute Asylum at Hartford, 33 per cent. had relatives afflicted in the same way. The statistics of the Pennsylvania Institution for the Deaf and Dumb, which have been carefully collected and collated by the special committee of investigation, covering a period of ten years, hardly bear out Mr. Bell's theory. Three hundred and forty families have in

this period sent children to this institution. In the case of six only of these families the parents are deaf, in five of the six congenitally deaf, and the total number of deaf children sent by deaf parents is ten; of these four were born deaf, and the other six became deaf by accident or disease. The same parents had twelve hearing children. In the case of the graduates of the institution, forty of them, twenty couple, have married since leaving the institution, sixteen of whom are known to have been congenitally deaf. To these twenty couples of deaf mutes there have been born, so far, just twenty children, of whom but two were born deaf.

Of the 364 graduates of the Pennsylvania Institution, whose record is given in detail in this report, 132 were born deaf, 232 lost their hearing from some adventitious cause, and of these 154 were deaf, as the result of some form of fever. The large number who became deaf from disease is accounted for by the fact that they were nearly all the children of poverty, which had brought with it the inability to secure timely proper medical treatment.

Dr. R. Mathison, Superintendent of the Ontario Institution for the Deaf and Dumb, at Belleville, writes: "As far as Ontario is concerned, Mr. Bell is very much astray in his theoretical conclusions." In this Institution there are the histories of 661 mute children, who are now or have been pupils since its establishment. He has acquaintance with the parents of about 300 of the children, and has made inquiries during the last five years of many of the others. Up to this time he has been unable to find that any of the parents were or are deaf and dumb. A few of the grand-parents however were mutes. A considerable number of deaf and dumb persons in the province are intermarried and have children, and in every case that has come to his knowledge the children can hear and speak." He further says: "That as the instances of hereditary deafness are so few in proportion to the number of deaf and dumb persons, and form such a small fraction of the population, an evolution of a distinct race of mutes need never be feared. Of the 661 cases above noted 262 were born deaf; the others lost their hearing by fevers, measles, colds, etc.

A rough calculation of the number of deaf mutes in the world is given in the *London Echo* to be from 700,000 to 900,000, and of these 83 per cent. are said to be born deaf, the others losing their hearing by different accidents. The number of deaf mutes in Great Britain is about 20,000. To meet the educational wants of these there are on the face of the globe 397 institutions, containing 26,473 inmates of both sexes, and employing over 2,000 teachers.

Excepting those who are immediately interested in and connected with the education of the deaf mute, there are few who fully appreciate the great amount of care, attention, and patience necessary that even the simplest principles of an intellectual education may be inculcated.

The theory that muteness does not always imply dumbness has given rise to much discussion as to the proper method of teaching deaf mutes, and of the two systems now employed leading writers on the subject are divided in opinion as to which is the better one.

Advancing science has taught that the organs of speech in a mute person can be developed to some extent if the muteness is the result of deafness and not of the absence of the organs of speech. In the latter instance the system of educating by articulation could not be of any avail, but all those who have the organs of speech should be taught, as far as possible, by articulation, and a thorough examination should be made of every pupil to ascertain this fact. Many of the most prominent institutions for the education of the deaf mute employ both methods, and the Pennsylvania Institution, of Philadelphia, one of the oldest and best managed schools of the kind in this country, has adopted both methods. And in the branch school at the corner of Clinton and Eleventh street, Philadelphia, under the management of the directors of the Pennsylvania Institution, the education of the deaf mute in this department is by articulation only. It is attended now, 1885, by seventy pupils, being recently changed from a day school to a boarding school, for the benefit of those living outside of the city. The principal, Miss Emma T. Ely, has nine assistants, and the school is managed with great success. Of deaf mutes now in the school many are far advanced, and compare in some branches very favorably with other children of the same age where the acquirement of knowledge has not been hindered by the loss of speech or hearing and who have had the double advantage of both eyes and ears.

The sign language, further than the simple letters of the alphabet, is not taught in the Pennsylvania Institution; and the system which consists in the formation of ideas by illustrations and observation, which the pupil is taught to write, has been adopted and is very successful in its results. It is

as interesting as the system of articulation, and also requires the same diligence and patience on the part of the teachers. When the pupil is sufficiently advanced in the knowledge of words and their meanings, he is then taught to read and study such branches as geography, physiology, history, and composition. In teaching by lip-reading or articulation, the pupil must learn to speak the word before he learns to write it. The pupils that have at one time had the power of speech advance rapidly, but the child that is born deaf not only has no knowledge of his power in this respect, but does not know what spoken words are when he utters them; but in spite of all these difficulties, is made, in time, to talk, and some of them surprisingly well.

The introduction of the improved methods and important changes which have recently been made by the Pennsylvania Institution, have attained highly satisfactory results. When we visited the school and were shown through the various departments by the principal, Prof. A. L. E. Crouter, a very proficient teacher, who by long and careful study of the best known methods, has become well fitted to fill the place of our friend Professor Foster, we found but one difference between it and other places of learning: this was the lack of covert whispering behind slates and around the corners of desks; the pupils were for the most part diligently at work, and the best order prevailed.

The following is an account of a deaf mute's* experience given by himself, whom we had the opportunity of knowing, and who was examined by ourself and Dr. C. T. Turnbull:

"At the age of fifteen years he enjoyed apparently good health, but was suddenly transformed into a deaf mute by *cerebro-spinal meningitis*, the result of a cold taken at a circus on a cold, rainy night. After remaining in an unconscious state for two weeks, he found his hearing and speech were both gone. On gaining strength, his voice partially returned, but his deafness was total. The usual remedies were applied, but without any apparent benefit. His friends all came to his rescue with catalogues, circulars, 'phones,' ear-drums and ear-trumpets, etc., and cures of every description; but a scientific treatment was deemed the best.

"He accordingly came to a Philadelphia aurist. All treatment proved of no avail, and after trying all kinds of instruments, he was advised to enter an institution for deaf-mutes to pursue his studies, and to take special care of his voice, and practice lip-reading as well as articulation. All this was very discouraging, and he was not inclined to enter an institution at first, but after some months did so. In the meantime, his voice improved by efforts to converse at home. On entering Columbia Institution, Washington, he was very favorably impressed, finding everything so different from his expectation. The text-books used were the same as in other schools. The sign language and dactylology were the means by which questions were asked and answered; also conversation and illustration were set forth. Instruction in lip-reading and articulation occupied a part of the time. He was taken in hand by a faithful and efficient lady teacher, and notwithstanding his inability to read a sentence spoken orally, in two weeks' time he was able to understand the greater part of what was spoken by the teacher, and a good deal said by those at home. Lip-reading was a great help, and gave him a great advantage."

He states: "Though not an expert at lip-reading, he can understand pretty much of what is said, especially at home and among friends, but cannot rely upon it as a means of conversing, and he does not think progress can be made as well by the oral as the combined method. His experience has not been great in this case, but he thinks he has seen sufficient to convince."

He further says: "If the public knew more of the manual alphabet, deaf persons would get along much better than they do now. After three years' experience, he finds but little disadvantage in being deaf."

CONCLUSIONS.

1st. When the deaf mute has the power of hearing at all, it should not be neglected, but should be improved as much as possible by means of hearing trumpets, etc.

2d. Physicians in charge of public institutions should prepare careful, accurate statistics as to the cause and condition of the ears of the deaf mute on entering and leaving the Institution, and what results to the hearing have been developed or improved by their efforts at treatment.

3d. It is an important matter that obstetricians and nurses should be carefully taught the anatomy and pathology of the ear, as the deafness of many of the so-called congenital deaf mutes is the result of mucus or blood in their meatus or tympanic cavity at birth. Another cause is physicians not attending in time to the catarrhal deafness, the result of cold from exposure or teething. The nurse

* Robt. Bell, Jr., 3d, Alexandria, Va.

is often at fault in placing the ears of infants in draughts of cold air, and allowing cold water to enter the meatus, pass back to the membrane, lodging there and causing acute inflammation, shown by intense pain and persistent earache, not relieved until perforation of the drum-membrane takes place or extension to the internal ear or brain.

4th. Then again, hereditary tendency to disease of the ear in tuberculosis and so-called rachitic scrofulous or syphilitic children should be watched from infancy to puberty so that every acute catarrhal attack commencing at the nose and extending through the Eustachian tube to the middle ear, producing deafness, should be carefully treated by the relief of pain, cleansing by a mild antiseptic solution or powder, followed by constitutional remedies adapted to the peculiar constitution* of the child. By these means we shall still further reduce the number of the so-called congenitally deaf mutes. I have found a most valuable aid for the relief of the deafness of little children after the acute attack, is the use by the mother of a tube to inflate the Eustachian tube, also to teach the child as early as possible to blow its nose, as by this latter means we often get rid of the mucus in the Eustachian tubes and pathway to the ear. The throat must also be attended to by applications to the nasopharyngeal mucous membrane.

5th. The only true plan to come to a definite conclusion as to the deaf-mutism being acquired or congenital, is to examine the outer and middle ear, Eustachian tube, and the sound-conducting apparatus with the throat, eyes and nose.†

Foreign Correspondence.

Paris Letter.

Paris, Dec. 18, 1885.

Eds. Med. and Surgical Reporter:

Pasteur is undoubtedly the hero of the hour; his experiments and inoculations, more frequently and correctly here termed vaccinations, against hydrophobia are monopolizing, to a large extent, the attention of scientific bodies.

As the question is largely discussed in your newspaper press, we need only mention the fact that Pasteur himself considers that only those cases where inoculation has been performed during the first ten days should be held in account when the efficacy of the operation is in question. The incubation of rabies is, in certain cases, as short as that period, but as the learned savant has become assured that his method is devoid of danger, he inoculates from two to six weeks after the patient has been bitten, and it is generally during that period, that is, from the twentieth to the sixtieth day, that the first symptoms of hydrophobia manifest themselves.

At the Académie de Médecine the principal objector to M. Pasteur's method was M. Guerin, well known in connection with the pansement ouaté. As this treatment may not have attracted much attention outside of France, it may be well to devote to it a few lines.

M. Guerin applies over large open wounds, such as compound fractures of the leg, for instance, layer after layer of common cotton wool, until the patient's leg is almost as thick as his body. Outside this he applies, with strong compression, the common linen roller in use here; and that is all.

The dressing is left in situ one, two, or even three weeks without changing; frequently the pus filters through, and forms a disgusting and ill-smelling mass. The results are however excellent; the patient, notwithstanding the presence of pus, rarely presents high fever, and recovers perfectly after severe compound fractures.

The newly appointed professor of diseases of children, M. Grancher, is one of the ablest clinical teachers in Paris. I passed one vacation season with him in Prof. Sée's service at the Hotel Dieu, and profited much from his clear and succint descriptions and methods of diagnosis. It is M. Grancher who performs the operation of inoculation for Pasteur; and, as might be expected from so great an admirer of that savant, he is an enthusiastic advocate of the germ theory.

In his inaugural lecture he boldly formulated the following declaration: "All morbid conditions of the human system have, as a starting point, either some microbe recognized or unrecognized, or some chemical alteration."

This doctrine would certainly simplify the study of general pathology, but does not accord sufficient allowance, particularly in infantile pathology, to the original condition of the individual himself, which has certainly a great influence in the development of contagious germs.

The second public annual séance of the

*See author's work on the "Hygiene of the Ear," 3d Ed. J. B. Lippincott & Co., Philadelphia.

†See the same work for the means of testing the hearing of the deaf mute.

Academy was attended by a numerous auditory, many ladies being present, who listened with marked attention to M. Proust's dissertation on microbes, which, according to his views, were present everywhere, but were generally innocuous. As is the custom at these public séances, he devoted a greater part of his discourse to the eulogy of two deceased members, M. N. Gueneau de Mussy and M. Robin, referring somewhat severely to the well-known obstinacy of the latter against admitting the germ theory in disease.

M. Rochard spoke feelingly and well of his compatriot from Brittany, the distinguished surgeon Chassaignac, whose extreme radical opinions and actions in the revolution of 1848 prevented his advance in the professorate, and did much to injure him as a practitioner.

One of the most popular of the agregés of the Faculty, who has done much to make the study of histology interesting, M. Mathias Duval, the author of the physiology of Küss of Duval, has been appointed professor of physiology, to succeed M. Robin.

In a report recently transmitted to the Conseil Academique of Paris, the dean of the medical faculty refers in a rather curious way to the mental and moral status of women graduates of medicine. He observes that many who enter do not graduate; the five years' study proves too long, and some marry or enter other occupations. M. Béclard calls particular attention to the statistics regarding lady practitioners in England. It is asserted that one-third of the number become insane, and he draws thence the following curious conclusion: "It is not probable that the statistician who compiled this table considers the practice of medicine as predisposing women to insanity, but he is perhaps of opinion that these women are originally of an eccentric turn of mind to adopt the profession at all."

Prof. Vulpian has recently experimented clinically with salicylate of lithia. He found it to be as efficacious as the soda salt in the treatment of acute rheumatism and gout, and much more so in those forms where the fibrous tissues are affected, and in those forms of subacute and chronic rheumatism, where the soda salt seems to have no effect. The usual dose to be administered is one drachm per diem, increasing by fifteen grains daily, until the symptoms are relieved. The taste of the lithia salt is not very disagreeable, although it contains a greater proportion of salicylic acid than the soda salt. Like the salicylate of soda, it may induce cephalalgia, ringing in the ears, and slight intestinal troubles, none of them of sufficient gravity to affect the general system.

M. Desnos has recently experimented with phytolaccin and juglandin; he found that in the dose of from two to four grains they proved efficacious purgatives and cholagogues, particularly the latter. The last séance of the Société de Therapeutique was largely taken up in discussing cocaine as a topical application to the throat in tuberculous ulceration, and to relieve the spasms of coughing in pertussis. M. Cadet de Gassicourt found a five per cent. solution efficacious, using the brush first on the soft palate, and then ten minutes later on the other parts of the throat.

M. Labbé remarked that he had obtained equally good results with the following lotion applied with the brush:

℞.	Tr. iodin.,	ʒjss.
	Potass. iodid.,	gr. xv.
	Tr. opii,	ʒj.
	Aquæ,	ʒijss.
	Glycerinæ,	ʒijss. M.

Ft. lotio.

There are this year twenty-two concurrents for the agrégation for the faculty of Paris, while for the provincial schools the number ranges from two to six. The cause of this apparent anomaly is the fact that a man who has spent the best ten years of his life as a student, interne and physician, in almost gratuitous service in the hospitals, does not like to bury himself in a provincial town, where the chances of gain for a man of talent are few. The effort to decentralize the study of medicine in France has thus far proven unsuccessful. ****

The Epidemic in Norwich, Ohio.

Eds. Med. and Surg. Reporter:

Dr. Myers reports from Martinsburg, W. Va., that they have had recently an epidemic of "a hybrid between malarial and typhoid fever." "The average duration was twenty-five to twenty-eight days." Temperature ranging from 100° to 103°. From the little he gives us of symptoms, I presume his cases are similar to an epidemic that prevailed in our small village during the months of August, September, and October. I, with others, would like to hear further from the doctor, for instance, as to temperature, state of pulse, condition of tongue, and treatment.

J. L. Geyer, M. D.

Norwich, Ohio.

—Castor oil applied daily for two or three weeks is said to be a sure cure of warts.

News and Miscellany.

A Typical Swell.

Thank God that all our young men are not like the following, who is described by the New York correspondent of the *Philadelphia Times*. Our *great* men are not made of such timber:

"He was dressed in the tip of fashion and a valet stood by his side, while the porter blacked his boots in the entryway leading to the Hoffman House bar-room. The young man threw the Irishman a half-dollar for the job, and then stepped to a table not far away, ordered a pint of champagne, drank it and sauntered out. 'You have just seen a perfect type of the young New Yorker,' said a friend, who knew the fellow who was so well dressed and who gave the bootblack fifty cents for a shine. 'He is a broker who is just blooming out for himself and has made a fat deal. Money is no object to him just now, and he is hunting any new vice or extravagance he can find. His life will not be long. If he succeeds for any length of time his dissipations will kill him, for, like most of his class, he burns the candle at both ends. He is only one of the many who help to make hotel life needlessly expensive. Chance has brought him a fortune, and it is handed out as easily as it came. If the man who polished his boots got fifty cents, the boy who served his breakfast probably received a dollar. While this practice gets him well waited upon, it compels other people to be equally extravagant or be slighted. This lavish tipping of waiters has become so common here that many times and in many places they make themselves positively disagreeable to guests who do not fee them with an open hand. This one is but a fair type of the swell business. He sits up all night, rises in time to get to his office, and pitches into the excitement of the day only half rested. Wine takes the place of sleep in keeping him in condition to do business. The average length of such life is only about ten years. Some may stand the whirl for fifteen, but the great majority have lost their vitality at ten, and either get broke or go out of the rush and hurry of the street.'"

A Pathetic Picture.

The New York correspondent of the *Philadelphia Times* thus writes to that paper:

"From the windows of the Manhattan Club the New York Hospital can plainly be seen. It is one of those charitable institutions which furnish a great deal of comfort to the poor as well as rich. I saw in one of its broad front windows to-day a strangely pathetic and beautiful sight. A woman, plainly dressed, with an almost death-like pallor upon her face, sat in a rocking-chair pushed almost against the pane. At her feet a little babe, with its arm broken, sat in a chair, playing with a rattle. Near her was a boy holding two other children, eight or ten years of age, one of them with its leg fractured and the other with its arm broken. The mother hardly took her eyes off the children, and the kind-hearted nurse, dressed in her neat calico frock and white cap, was moving backwards and forwards like an angel of mercy, bringing comfort to the stricken little ones. There was such a broad touch of pathos in the picture that a dozen club men, pushed from the whirl of business, paused to look at the striking group in the hospital window. It was one of those sights which touch the heart of the sternest, and in only a few moments quite a purse was made up for the little sufferers. I watched the scene for some time, until one of the directors of the splendid charity was introduced, and he took me over to this home for those who are injured by accidents. The picture was not lightened by close contact, for just as I had reached the inside and was looking at the unfortunate children, the nurse tapped the mother on the shoulder, and said: 'You must go now.' The great brown eyes, set on their framework of white, filled with tears as she arose, kissed the little ones, and went to her cheerless home, for she was evidently very poor."

The International Medical Congress.

To show which way the wind is blowing, we quote the two following letters from the *New England Medical Monthly*, January 15:

"I feel in hearty accord with the sentiments expressed by your correspondent in the November number of *The Monthly*, on the matter of the coming meeting of the International Medical Congress. There is no doubt but that the friends of the original committee, have used every means in their power to misrepresent the action of the new committee, and to belittle its efforts to make the Congress a success. I wonder if the journals which are supporting this sort of thing are not waking up to a sense of their being on the wrong side of the fence. I know where one of them lost four subscribers in this city since the raid began. Is not this a straw which shows which way the wind is blowing? A Subscriber.

"*Providence, R. I., Dec.*, 1885."

"The note in the last *Monthly* from a doctor who signed himself 'Not a Member of the American Medical Association,' has touched the keynote of the whole International Medical Congress business. When a committee appointed by any organized medical body insults its constitutors, as did the original committee headed by Drs. Billings and Hayes, by appointing every one of themselves to offices, and prominent ones too, and some of their members to several offices, we think it is time for the profession to call a halt. A few have followed the original committee; the *mass* of the profession are behind the new committee, staunch and true. Let them rave, rant, revile, and misrepresent; they are the only ones who will suffer, not the International Medical Congress.

"A Member of the A. M. A.
"*Portland, Me.*"

Pasteur.

The *London Med. Times* says that M. Pasteur still pursues the course of his experiments, and nearly seventy persons bitten by mad dogs have been inoculated at his laboratory. There has been some talk of creating a "clinique" for M. Pasteur and his rabid patients. The proposal, however, has been hitherto non-suited, upon the ground that the celebrated bacteriologist is not a medical man, and, holding no diploma, has no legal right to practice. It might also be said that, before lending the weight of official authority to the system of inoculating hydrophobia, it might be as well to let the matter be well tested, the proposition in itself being at least rather startling, to say nothing more. At all events, the friends of "progress," who are always ready to cry loudly against persecution, cannot, in the present instance, inveigh against government, which has certainly allowed more liberty to M. Pasteur for the prosecution of his experiments than he would have found on this side of the Channel.

The *Gazette Hebdomadaire* states that, since M. Pasteur's announcement, the prophylaxis of hydrophobia has occupied the attention of all Paris, in the press, the societies, and the salons, the impressions varying from enthusiasm to skepticism. Fortunately, the most prudent and the wisest of all who occupy themselves with M. Pasteur's investigations is M. Pasteur himself, as shown by his statement of his views before the Conseil d'Hygiène. In possession of a method which at all events has been very successful among animals, he has believed himself authorized to extend its application to man, but he is the first to admit that time must be given to form a final judgment upon the matter. In the meantime, patients are arriving from all parts, including Algeria; and, in spite of the length of time that may have elapsed since the bite, M. Pasteur undertakes the cases, in the hope that the inoculation may still be effective five or six weeks, and perhaps longer, after the accident. Experience can alone decide this point. In the meantime there is a sufficiency of virus in the laboratory, and this is kept up by daily inoculations; but if the present eagerness continues, a special institution will become indispensable.

Disinfection of Rags.

Dr. J. Howard Gaylord, of Baltimore, Chairman of the Special Committee on Disinfection of Rags, reported to the American Public Health Association that it is an admitted fact that the importation of rags is a prolific cause of the spread of infectious diseases, and that ports of entry are the gateways for their introduction. Foreign disinfection was not to be relied upon, and the committee proposed that a resolution should be passed by the Association that all health authorities having jurisdiction over matters connected with maritime systems of disinfection, should thoroughly destroy all germs before the rags are permitted to be distributed for manufacturing purposes.

The report was, after a prolonged discussion, recommitted for further investigation by the committee during the coming year, and Dr. J. H. Raymond, of Brooklyn, and Dr. Joseph Holt, of New Orleans, were added to the committee.

Observations on the Cape Fear River Water as a Source of Water Supply.

Before the American Public Health Association Dr. Thomas F. Wood, Secretary of the State Board of Health of North Carolina, narrated the experience of a company formed to make artificial ice by the ammonia process. They used the water of the Cape Fear River, which was boiled and the steam condensed, and the condensed water used for making the ice. It was found that the ice had a decidedly greenish color, and an odor of tar and creasote, and that a core formed in the centres of the frozen cakes which was highly impregnated with these wood products, and this in spite of every care being used to keep the water in the boiler as fresh as possible. An examination into the cause of this showed that the river water was impregnated, to a certain degree, with substan-

ces capable of yielding these products when they underwent a process of destructive distillation in the boiler. The trouble disappeared only when well water was used and the river water wholly abandoned.

An Attack on Pasteur.

The London correspondent of the *Jour. Am. Med. Ass.* says that M. Henry Rochefort is never happy for a long time, if some one, or some thing, is not attacked in his organ. This paper has made itself remarkable by the acerbity with which it has attacked M. Pasteur, whose equanimity, however, is not disturbed. A week or so ago it printed a sensational paragraph concerning a tragic incident which it affirmed had just occurred in Paris. A child six years of age who had been bitten by a mad dog was placed by her parents under M. Pasteur's care; and, as the paper asserted, had lost her life in consequence of his treatment. As a matter of course, the absolute correctness of the story was vouched for, defying M. Pasteur to contradict it. It turns out, however, that it omitted to state the real truth, which very materially alters the circumstances of the case related. The little girl placed under M. Pasteur's care met with the accident which proved fatal six weeks before he was consulted. The dreaded malady—hydrophobia—had consequently time to develop itself; and the case, evidently, cannot be accepted as furnishing a proof against the value of the distinguished savant's theories.

The Discovery of Auscultation.

The *Virginia Med. Monthly* tells us that "Lænnec told one of his friends that he discovered the principle of auscultation thus: One day, in the court of the Louvre at Paris, he noticed children amusing themselves by holding a cylindrical piece of wood to the ear, and scratching with a pin the farther end. Thus they heard a louder noise than the pin usually produces. At his next visit to his patients in the Hospital Necker, he made a hollow cylinder out of a roll of paper, and applied it over the heart of a patient. This was the first stethoscope. After a time, he used one made from cedar-wood. In 1819 he published his treatise on Mediate Auscultation."

Vaseline in Pastry.

M. Dubois, in a communication to the Société de Biologie, stated that, wishing to ascertain whether vaseline is injurious, and its use ought to be prohibited in pastry, he fed two dogs on soup exclusively made with vaseline. The animals did not present any symptoms of gastric disturbance, nor imperfect nutrition. Their excrement was slightly yellow; their weight was not altered; the slight diminution of urea observed in their urine was explained by the absence of meat from their diet. M. Dubois concludes that pastry made with vaseline may not be pleasant to the palate, but that it is not injurious to the health.

American Public Health Association.

OFFICERS FOR ENSUING YEAR.

President—Dr. Henry P. Walcott, of Cambridge, Mass.

Vice-Presidents—Dr. C. W. Covernton, of Canada; Dr. G. B. Thornton, of Memphis, Tenn.

Treasurer—Dr. J. Berrien Lindsley, of Nashville, Tenn.

Executive Committee — Dr. Pinckney Thompson, of Kentucky; Dr. Henry B. Baker, of Lansing, Mich.; Dr. Joseph Holt, of New Orleans; Dr. Charles Smart, U. S. A.; Dr. C. N. Hewitt, of Minnesota; and Dr. H. A. Johnson, of Chicago.

Secretary—Dr. Irving Watson.

The British Medical Association.

We learn from the *Medical Times and Gazette* that Dr. Austin Flint has consented to deliver the address in medicine at the next annual meeting, which is to be held in Brighton on the 10th, 11th, 12th, and 13th of August. The American profession will appreciate the compliment to our country implied in the invitation to Dr. Flint, and we trust that the distinguished President of the next International Medical Congress will enlighten our English cousins in reference to it.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED JANUARY 2, 1886.

Guitéras, John, passed assistant surgeon. Upon expiration of leave of absence, to reassume charge of the service at Charleston, S. C., December 29, 1885.

Tattic, J. B., assistant surgeon. Appointed an assistant surgeon December 28, 1885. Assigned to duty at Baltimore, Md., December 29, 1885.

Items.

—Several correspondents in the *Lancet* have lauded hydrastis as a most useful drug in dyspepsia.

—We refer our readers to an extract from Ziemssen's Cyclopœdia by the celebrated Professor Juergensen, on Catarrhal Pneumonia, on third page of cover.

—A letter from Berlin to the *Therapeutic Gazette* reports the case of a girl of eight with gonorrhœal rheumatism, communicated by connection with a boy of twelve.

—In *L' Union Medicale* is reported a case where a woman was confined while her husband was suffering from a mild facial erysipelas. There followed a fatal attack of puerperal septicæmia.

—M. D'Arsonval has shown that the nerve of the frog, hitherto regarded as the most perfect of galvanoscopes, is 200 times less sensitive than the telephone. In consequence of this property, several physiologists now employ this instrument in their researches.

—Dr. Guichard, of the Maternity Angers, records the following case: A stoker of a railway company had erysipelas of the face, which declared itself on January 15th, and was cured on the 30th. His wife was delivered of a child on January 17th, and died on the 30th of that month from puerperal septicæmia.

—Demange says in *L' Union Medicale* that diabetes insipidus is best treated by valerian in doses of two to four drachms of the powder per diem. This drug was highly praised by Trousseau, and has been revived since by Bouchard. Excellent results are also claimed from the use of electricity, in the form of the constant current applied over the spinal column.

—In a case of alleged epithelioma involving the facial bones, with extensive infiltration of the tissues, where an operation was not deemed desirable, Dr. Antonio, of Mazzara del Vallo Maggio, applied an ointment consisting of fifteen parts of resorcine to twenty parts of vaseline twice a day, with the result, it is said, of completely curing the disease, nothing remaining but a white scar a centimetre in diameter.

—Dr. Edward Pritzel, of Vienna, reports the case (*Wiener Medizin Woch.*) of a young woman, aged twenty-six years, who entered the maternity hospital of Prof. Braun.. It was found that she was very susceptible to hypnotic influence, and when her labor came on, as it was slow and painful, she was hypnotized. While in this state of artificial anæsthesia the child was born, with no pain and with but slight loss of blood.

—Dr. C. G. Roehr, of Milwaukee, Wis., writes to the *Med. Record* that he has used peroxide of hydrogen, with excellent results, as a disinfectant and stimulant to old ulcers and sinuses. When injected into sinuses containing exuberant granulations it destroys these, leaving uninjured the healthy tissues. There is very little pain, and a rapid improvement ensues.

—Small-pox is very prevalent in Vienna; and, in consequence, orders have been given for the vaccination of soldiers in barracks; and the municipal authorities have issued urgent appeals to proprietors of schools, workshops, and employers generally, to have the children, servants, or working people under their charge, vaccinated. In Berlin, where revaccination is now universal, small-pox has for some years been almost completely stamped out.

—The prize of eight thousand francs offered by the Belgian Academy of Medicine for an elucidation by clinical facts of the "pathogenesis and treatment of diseases of the nervous centres, and principally of epilepsy," has not been awarded; but a sum of five hundred francs is offered by way of encouragement to the author of the essay bearing the motto, "Traditionem pondero, doctrinam respicio, sequor veritatem," on condition that he allow his essay to be printed in an abridged form with the criticisms of the Commission.

—The Russian members of the Committee for Collective Investigation of Disease, appointed at the International Congress of Copenhagen, have begun their work. They publish a long circular in a recent number of the *Russkaya Meditsina*, setting forth the object of the committee and explaining the method to be pursued. A list of questions is appended for the guidance of those willing to aid in the work. The first subject proposed for collective investigation is the etiology of rachitis. The members of the committee are Rauchfuss, of St. Petersburg, and Runeberg, of Helsingfors.

QUERIES AND REPLIES.

MESSRS. EDITORS:

Has any member of the profession ever advanced the idea that diseases peculiar to the female sex are prolonged and kept up by little living (microscopic) organisms?

Ans.—There is scarcely a disease known to man—or woman either—that the germ theorists have not claimed. Abnormal vaginal or uterine discharges have been repeatedly attributed to microscopic growths.

ENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle pleasantly flavored. Retail $1.00. All of it pure pepsin.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1505-1556

THE HIGHEST AWARD.

THE GOLD MEDAL,

HAS BEEN GRANTED TO

MELLIN'S FOOD

FOR INFANTS AND INVALIDS,

At the World's Exposition, New Orleans, 1885.

A Sample of MELLIN'S FOOD, sufficient for trial, will be sent free to any Physician desiring it.

Lecture.

THE TREATMENT OF VOMITING.*

A CLINICAL LECTURE BY DR. DUJARDIN-BEAUMETZ,
Of Paris, France.

Under the head of atonic dyspepsia, we have studied the consequences of enfeeblement of the contractile power of the muscular coat of the stomach; we are now to consider another modification affecting this muscular investment, attended with perversion and exaggeration of its movements; phenomena which manifest themselves by the rejection of alimentary matters contained in the stomach. And since we are frequently to meet this symptom in the course of these studies, permit me here, in a general manner, to discuss the therapeutics of vomiting. Do not think, moreover, that in doing this I am digressing from my subject. Deven has in fact said that vomiting never takes place in a healthy stomach, but that, apart from toxic and other irritant causes, it is always due to dyspepsia of more or less long standing. Although this opinion, taken as a whole, may seem a little exaggerated, it nevertheless applies to a great many cases of vomiting.

Vomiting, you know, is characterized by the sudden expulsion of substances contained in the stomach, resulting not only from the abnormal and exaggerated contractions of the muscular coat, but also, and especially, from the simultaneous contractions of the diaphragm and muscles of the abdomen, the whole constituting a true reflex act, which may have its point of departure in variable regions of the economy.

In this definition of vomiting, I have assigned the important part to the stomach and the contractions of the abdominal muscles. This is a view which I am well aware is not adopted by all the physiologists, and when you consult the writings of Boyle, Schwartz. Hunter, and especially those of Magendie, you will see that these authorities ascribe but a secondary rôle to the stomach. At the same time, on reading attentively these memoirs, you will observe that the experimental researches which have been made show only this: that when the stomach is removed from the influence of the abdominal muscles and diaphragm, vomiting does not take place; but this is no reason for denying to the muscular coat of the stomach all participation in the ordinary act of vomiting.

Scheff shows, on the contrary, that the stomach takes an active part in vomiting, that under certain circumstances the normal movements of the muscular coat of the stomach, which habitually take place from left to right, that is to say, from the great tuberosity toward the pylorus, may take place in an opposite direction, and force the contents of the stomach from the pylorus toward the cardia.

If we quit the domain of physiology for that of clinical experience, we shall find indubitable evidence that the stomach by its mucous and muscular coat, plays an important part in the mechanism of vomiting, and that in this complex act the abdominal pressure is far from being the only factor. Here, for instance, are two patients; the one has a very severe bronchitis, with incessant fits of coughing, and yet, despite all these paroxysmal efforts of the thoracic and

* From advance sheets of a forthcoming work.

abdominal muscles, he does not vomit; by his side is a phthisical patient, who has but few fits of coughing, and yet whenever the cough comes on, he vomits his food. How do you explain this difference? In the case of the one the functions of the muscular and mucous coats of the stomach are intact, while in the other the existing dyspepsia explains the facility of the vomiting under the least pressure of the abdominal muscles.

Recall to your minds that curious, almost unique, case which you observed in this hospital in No. 15, ward St. Lazare. I refer to a certain patient who, with the intention of suicide, had swallowed a caustic liquid; you remember that the autopsy of this patient showed us almost the entire stomach—mucous and muscular coats—transformed into a vast eschar; and for eight days he lived thus, drinking a great quantity of milk, and without once vomiting in all this time. Here the transformation of the walls of the stomach into a non-contractile and insensible eschar sufficiently explained the absence of the vomiting.

While, therefore, I am free to admit in explanation of the mechanism of vomiting, the preponderant *rôle* assigned to the contractions of the abdominal muscles, I must also insist that the muscular amd mucous coats of the stomach have an important part, and that perfect integrity of the functions of these membranes is antagonistic to the act of vomiting.

I have said that the reflex act, which is called vomiting, has for its point of departure variable regions of the economy. We will now examine into these different sorts of vomiting, and the treatment which should be opposed to them. It seems to me most advantageous to give you, first of all, the general therapeutics of vomiting, applicable as they are to nearly all cases, and to reserve for a special description the remedial means necessitated by the different varieties of vomiting.

An important place must here be given to dietetics. Experience has demonstrated the efficacy of iced drinks, effervescent waters, and abstinence from all food, whether solid or liquid. Recommend the employment of a mixture of milk with ice and seltzer-water, which may be sucked in small quantities through a straw or pipette. With these means you can associate internal and external medication.

Among the pharmaceutical means we have first the potion of Riviere, which bears a marked resemblance to the *mistura effervescens* of the United States Pharmacopœia. This potion, as you know, consists of two parts. There is No. 1, which is alkaline, and No. 2, which is acid. You give the patient first a tablespoonful of the alkaline solution, and immediately follow it by the same quantity of the acid potion. Then come the preparations of opium and belladonna, and here you may advantageously avail yourselves of the hypodermic method for the introduction of morphine and atropine. Medicinal lavements have been recommended, but it must be confessed that this method generally fails, on account of the efforts of vomiting not permitting these lavements to be retained; you can, however, utilize the rectum for your opium and belladonna suppositories, which are better retained.

To this treatment, you may add the use of plasters, applied to the epigastric region. Gueneau de Mussy has long insisted on the happy results which may be obtained from the employment of this means in obstinate vomitings. You can make use of the diachylon plaster with or without belladonna; the emplastrum thereacæ, or the opium plaster, all may render you service. Finally, with still greater prospect of benefiting your patient, you may resort to revulsives applied over the stomach, such as sinapisms, vesicatories, and the cautery.

Such, gentlemen, are the general means to employ in the treatment of vomiting, from whatever cause it may arise. Let us now take up the consideration of certain species of vomiting. We have, first of all, dyspepsia with vomiting predominant. In fact, certain persons vomit with a strange facility; the least error in diet, a little food badly borne, too strong a smell, exercise a little too energetic, a keen emotion—all this, in these patients, manifests itself by vomiting. As the rejection of food is a common symptom in all forms of dyspepsia, you will have, first of all, to combat, by appropriate means, the dyspepsia; then you will be able to employ against the vomiting the different pharmaceutical means which I have just enumerated. Hyposulphite of sodium, and salicylate of sodium, have also been recommended to combat certain kinds of acid vomiting, where one often meets a peculiar alga, which Goodsir was the first to find, the *sarcina-ventriculi*. These substances have for their end to destroy these parasites, whose intimate action in the production of vomiting, despite the researches of Windmuller, is far from being clearly defined.

As for directions respecting diet, much judgment is required in the selection of the

proper food, and you will often have to be guided rather by the caprice or idiosyncrasies of the patient than by the most carefully formulated scientific considerations; for nothing is more strange and unaccountable than the way different persons are affected by different aliments—one who, for instance, vomits substances the most digestible, will often tolerate without inconvenience substances that are really indigestible.

Then we have a particular condition in which vomiting plays an important part, a condition which is temporary, but which may be the cause of more or less serious evils—I allude to sea-sickness. Although we are ignorant of the primary cause of these vomitings, a cause which is without doubt multiple, and in which we have the influence of sight, smell, and modifications produced in the equilibrium of the abdominal viscera, it is nevertheless a form of sickness which is very common, and which every physician will be obliged to treat.

It has been recommended to support the abdominal parietes by a broad bandage, whose object is to prevent the displacement of the intestinal mass; I think that small results must follow this means.

Another mode of treatment has been scientifically tested; I refer to the chloral treatment. Geraldes was the first to recommend this mode of managing sea-sickness; after trying it on himself, he adopted a hint which he obtained from Pritchard and the London *Lancet*. Being called to England on business, and having suffered in all his previous voyages from protracted vomitings, he took a draught of chloral, and had no more vomiting. Since then this practice has become general, and the physicians of the Transatlantic Company and the navy surgeons derive great benefit from the chloral treatment of sea-sickness. The chloral is taken at the moment of the departure, the dose, which may be given in potion or in syrup, being from 15 to 45 grains. If the patient suffers from thirst, you can advise him to drink iced champagne, which is also indicated to combat the vomiting. Dr. Garepuy has also employed the same treatment in cases of land-sickness; I refer to that vertigo and those attacks of vomiting which some persons experience when they are subjected to any trembling movement, whether of carriages or of railroad cars.

You can also use in sea-sickness another means which has given good results: I refer to injections of morphine. The Baron of Theresopolis is one of the strongest advocates of this mode of treatment, and he cites a great number of observations where these injections have caused disappearance of all the grave accidents caused by sea-sickness. Dr. Philippe Vincent also commends these injections in sea-sickness.

You should be very sparing in the use of these injections, and watch attentively their effects. Morphine, in fact, determines of itself in some persons severe and prolonged vomiting. In those cases where the injections of morphine are badly supported, you can sometimes advantageously make use of the mixture of which I have spoken to you before, and in which atropine is combined with the morphine. It is especially in these vomitings which have for point of departure an intense pain, whether in the stomach or in some other organ of the abdominal cavity, that you will derive benefit from these injections of morphine and atropine.

Among the organs which have a direct influence in causing vomiting, the uterus is pre-eminent, and we see certain metrites, certain uterine congestions and ulcerations, accompanied by this symptom; but it is principally in pregnancy that these vomitings are, so to speak, the rule.

This vomiting is more likely to supervene during the first four months of gestation. It is an inconvenient and painful symptom for which the physician is often consulted, but which has ordinarily little gravity. Sometimes, however, this morning sickness acquires a formidable intensity and persistency, and one finds himself in presence of incoercible vomitings, which if not combated in time by an energetic medication, and even by the intervention of the accoucheur, may end in death.

It is desirable, then, that the physician shall have at hand powerful therapeutic means to combat these vomitings; and, without going farther into the subject, which would require for its complete treatment details which you will find in the special treatises and text-books of obstetrics, I shall set forth the different measures to which you may advantageously resort. Here everything has been tried, everything has succeeded, and everything has failed; hence the list of remedies is a long one.

In the first rank, we have the alcohols, which Bouchardat has vaunted, and which are in common use in the treatment of the vomitings of pregnancy. I have even seen pregnant women who before had a great repugnance to spirituous liquors, not only bear them well during this period, but even long for them. And here, gentlemen, it is just

those alcohols which are the strongest which give the best results. You will then prescribe whisky, rum, cognac, and especially the elixir of Grande Chartreuse,* which may be taken in the dose of a few drops on a lump of sugar.

By the side of these remedial measures you have a medicament which also gives good results, and which our regretted friend, Dr. Gross, long ago recommended: pepsin given in the dose of from 5 to 10 grains has sometimes arrested the most obstinate vomitings.

(To be continued.)

THE EFFECTS OF COCAINE ON THE CENTRAL NERVOUS SYSTEM.†

BY D. R. BROWER, M. D.,
Of Chicago, Ill.

We have recovered from the primary effects of the brilliant discovery of Dr. Carl Koller, that sixteen months ago electrified the medical world, and can now reason together calmly and dispassionately about this powerful therapeutic agent.

I have been using in private and hospital practice the preparation of the coca leaf for about six years, and for about one year past the alkaloid cocaine, and have reached certain conclusions as to its beneficial and its baneful effects on the central nervous system, that I propose to present for discussion in this paper. I say beneficial and baneful effects, for my first proposition is, that it is as powerful for evil as it is for good.

First. Its effect upon the brain.—In small doses, that is, three or four drachms of the infusion, or one-half to one grain of the alkaloid, it is the most certain and agreeable of all cerebral stimulants. It increases the frequency of the pulse and respiration, and elevates the body temperature. It gives a sense of well-being, a freedom from care, and a pleasant mental exaltation. The first effects of the drug is upon the cerebrum, then upon the medulla oblongata, the sense of mental exhilaration preceding the stimulation of respiration and circulation. In small doses it also stimulates the spinal cord, producing a desire for muscular activity, and increasing activity of reflexes.

The effect upon the spinal cord, according to the experiments of Dr. Alexander Bennet,* are due entirely to its effects upon the posterior column of the spinal cord; an observation that may make the drug useful in locomotor ataxia. I am now making clinical investigation in this direction.

This increased activity of the central nervous system is usually followed by a quiet, composed, self-satisfied condition of the mind and body, that eventuates in sleep. These agreeable effects are accompanied with a loss of appetite, frequently with nausea, constipation, and diminished activity of the kidneys, of the sexual functions, and of the skin. In large doses, two to ten grains of the alkaloid, there are produced tinnitus aurium, photophobia, illusions, hallucinations, great loquacity, and a marked tendency of the mind to exaggeration and misrepresentation. If continued for some time, this dose produces perversion of the affections, a disturbance of the moral emotions, a tendency to quarrel with friends and former associates, and to form alliances with persons formerly regarded as inferiors.

This state of the nervous system may become very like delirium tremens, with the same kind of muscular tremor, and the same kind of horrible hallucinations. During this time the loss of appetite and diminished activity of assimilation result in extreme pallor of the face, dryness of skin, extreme constipation, very much diminished urinary excretion, loss of sexual function, and great emaciation.

Second. Cocaine in the Alcohol and Opium Inebrieties.—Much has been written upon the use of this drug in efforts to cure this form of nerve mal-nutrition. Lewis Bauer, M. D.,† in an admirable article, details his experience with it in a case of alcohol inebriety. He began with one-fifth of a grain, which the patient soon increased to ten grains by hypodermic injection, with the same disastrous result upon the nervous system as has been mentioned; but he expresses the opinion that cocaine inebriety was less objectionable than the alcoholic.

Dr. Erlenmeyer‡ gave it, in various doses, in 236 cases of opium inebriety, and expresses sentiments that entirely agree with my own. He says that while cocaine does modify and mitigate the phenomena of opium abstinence, its effect is only transient and of brief duration; he regards it of trifling value as a substitute for morphine.

Dr. J. T. Whittaker‖ reports, in an elab-

‖Medical and Surgical Reporter, August 15, 1885.

orate paper, the results from its hypodermic use in two cases of opium inebriety, that were satisfactory. Dr. Palmer, of Louisville, Ky., who was one of the first to advise its use in such cases, continues to be an enthusiastic advocate of the drug.

My own experience is against its use in either of these inebrieties; it undoubtedly makes the withdrawal of either of these agents much easier for the patient, because its effects are so similar to opium and alcohol that he scarcely feels the need of either; but you place within his reach an agent much more rapidly disastrous and destructive to the nutrition of the cerebral convolutions; an agent that will soon sink him to a degradation much lower than is possible with either of the others.

Third. Cocaine in Melancholia. — The best results yet obtained from the administration of the drug have been in conditions of mental depression. Dr. Jerome K. Bauduy,* in a valuable paper read before the American Neurological Society, June 17, 1885, relates a very extensive experience with the drug in melancholia. His method was to inject one grain of the muriate of cocaine, and he frequently witnessed the morose, silent, taciturn patient, a prey to the most profound grief or sadness, recover his normal self, begin to talk about his case, and wonder how he could ever have experienced such gloomy ideas. He reports one case of suicidal melancholia which recovered in less than one month, and to whom he only gave five injections of cocaine. Dr. Alexander B. Shaw,† in an able paper on the uses of the drug, speaks with the same degree of positiveness of its value in the insanities with depression.

My own experienee with cocaine in this form of insanity is in accord with Drs. Bauduy and Shaw, although the bad effects of the drug upon the digestive and assimilative processes, and upon the secretions, have frequently disappointed me in its use. I have observed his valuable suggestion of giving the drug several hours before eating, in order to avoid the anorexia and nausea, but even with this precaution I have frequently found it impossible, while using it, to give that great abundance of food, systematic feeding, which, after all, is the most valuable therapeutic measure in the relief of melancholia.

Then again, the excretory organs are often at fault; indeed, often the foundation of this form of insanity, the mal-nutrition of the brain being due to the accumulation in the blood of the waste product of tissue metamorphosis. In such cases the further depression added to those vital necessities by cocaine, must more than counteract the beneficial effects of cerebral stimulation. In such cases alteratives and stomachic tonics added to the treatment may make it successful.

I recall two cases of profound melancholia. One, a physician, aged 45, from a neighboring town of this State; an uncomplicated case, the result of excessive professional work in a large country practice. He received the cocaine in one-grain doses three times a day, with pil. hydrargyri, aloes, and strychnia. His recovery was rapid, and has continued for four months. The other case was that of a woman aged 48, from Indiana, laboring under melancholia, that seemed to have its origin in the fret and worry induced by a tumor of one of the mammary glands. Under this combined treatment she recovered about as rapidly as the case detailed by Dr. Bauduy. In both these cases the drug was administered in pill form, and probably because of its combination did not interfere with the free use of egg-nog and other concentrated food in large quantities.

I have now under treatment a case of melancholia in which I am using the drug with the atomizer, using about four grains a day, on the nasal mucous membrane. The stimulating effects on the brain are manifested in a very few minutes after it is used. I am of the opinion that cocaine is the most valuable recent addition made to the therapeutics of melancholia, especially if its bad effects are guarded against in the way suggested.

Fourth. Neurasthenia. — Cocaine is of value in the treatment of this tedious and perplexing derangement of the nervous system. Dr. J. Leonard Corning.* in his scientific review of the cerebral form of this disease, calls it "the remedy *par excellence.*" Dr. William Oliver Moore,† in a very valuable paper on the physiological and therapeutical effects of coca and its alkaloid, gives his personal experience and the observations of others as to the value of the drug in all depressed conditions of the nerve-centres, as well as its effects upon himself in various doses.

My experience coincides with the testimony of these writers, but I observe the same care in sustaining the digestive function and stimulating the eliminations as

*New York Medical Journal, Sept. 26, 1885.

†The Weekly Medical Review, vol. xii., No. 17.

*Brain Exhaustion.

†Quarterly Bulletin, New York Post-Graduate School, Vol. i., No. 2.

stated before. Cocaine, as mentioned in the beginning of this paper, is as powerful for evil as for good, and it requires no special prophetic gift to say that more disastrous results will be experienced by the laity from its indiscriminate use than have been known from either opium or alcohol. Indeed, its action upon some persons in moderate doses is alarming. Dr. G. W. Kinnicutt* relates a case of poisoning from three and a third grains of the drug applied to the nasal mucous membrane, in the case of a female aged twenty-five, who had been using it for hay fever. When he arrived, she was in an alarming comatose condition, from which she recovered in about three hours, under the liberal use of brandy, ammonia, and digitalis, with heat to her extremities and epigastrium.

Dr. J. Spear,† U. S. Navy, publishes a case of alarming coma closely simulating opium poisoning, in a private, U. S. M. C., aged twenty-nine, the result of the hypodermic use of ten grains in divided doses, extending over about twelve hours. The case was supposed to be opium poisoning, and was treated with atropia, coffee, and flagellation, and in about nine hours he recovered from the immediate effect of the poison. Dr. T. H. Burchard ‡ gives an account of a case in which the hypodermic injection of four-fifths of a grain produced a sudden and complete loss of consciousness, and in which respiration stopped, and the radial pulse was scarcely perceptible. Artificial respiration, hypodermic injection of one-twelfth grain of atropia, and sinapisms to heart and extremities, relieved the patient. Fifteen minutes after the prostration, the pulse was forty-eight and feeble, the respiration seven or eight, and the pupils contracted. Unconsciousness continued about twenty minutes.

Dr. Merriam§ relates the case of a gentleman who had been taking cocaine for four months for sick headache, beginning with about two grains a day, and gradually increasing till he was taking from ten to fifteen grains daily. He was very weak, with a pulse of 100, and his mind wandering somewhat as in delirium tremens. Drs. Bauduy and Shaw, in their papers already mentioned, dwell especially upon the dangers of the continued use of the drug in large doses. My experience is in accord with these several observers. Several cases of the poisonous effects of the drug have been under my treatment during the past six months, and I will call the attention of the Society to two of these cases, both physicians:

First. The case of Dr. W., aged about thirty, of excellent physique, of neurotic tendency by inheritance, who began the use of the hydrochlorate of cocaine upon the nasal and pharyngeal mucous membranes for hay fever. He gradually increased the dose to five grains taken in one dose in the evening, when his attack of hay fever was usually most distressing. This dose gave almost immediate relief from the hay fever, and gave a sense of mental stimulation very like champagne. He was almost at once seized with a desire for brain work, and would pass the greater part of the night reading and writing on professional topics, experiencing a keenness of perception and a mental vigor greater than normal. He describes his sensations during the period of activity of the drug as exceedingly delightful. Towards morning he would fall aslsep, and on the next day he would have no appetite and but little desire for work, the excessive stimulation having been followed by a corresponding depression of the vital forces.

He soon found a very irregular and rapid action of the heart, and passed by rapid stages to a condition of deplorable neurasthenia, from which he is slowly recovering. He had the same derangements of digestion, assimilation, and elimination that have been already mentioned. He had but little desire for food, a thickly coated tongue, a feeble digestion, considerable emaciation, urine scanty, and much of the time loaded with uric acid and urates, with dyspnœa and the irregularity of heart action before mentioned. The stools for some time were chalky, skin dry and pallid, pupils dilated, reflexes, especially the patellar tendon, much increased, and muscular powers much diminished.

He continued the use of the drug about ten days, and stopped it because he feared its enslaving power. This profound depression of the nervous system followed immediately upon its stoppage. The agents used to overcome this neurasthenia were an abundance of easily-digested food, mild alteratives, moderate alcoholics, strychnia in small doses, cinchona, and the compound syrup of hypophosphates. As stated, the depression is gradually passing away, but the ten days' use of cocaine has incapacitated him for four months from the practice of his profession, and the probability is that at least three months more will be required to complete his restoration.

† The Medical Record, Nov. 14, 1885.

‡ The Medical Record, December 5, 1885.

§ Quoted by the Medical Record, Nov. 28, 1885, from Ohio Medical Journal.

Second. The case of Dr. B., aged thirty-five, a man of decidedly neuropathic temperament, a hard-working, conscientious, and skillful physician, in the enjoyment of a fair but very laborious practice, with an excellent family history. Three years ago, with my assistance, he discontinued the use of opium, which he had been using excessively. He began the use of cocaine last May in one-eighth grain doses, having been led to believe it to be a harmless stimulant, and being at the time much run down by excessive professional work. It gave him such a sense of well-being as he had never experienced from any agent before, the sense of complete repose and self-satisfaction it produced being very much more marked and agreeable than than that derived from opium. He gradually increased the dose until he consumed about fifteen grains a day by hypodermic injection. The large doses soon began to produce mental disturbance; he became irritable, quarrelsome, impetuous, and considered himself to be possessed of a mission, and that to revolutionize the medical practice, claiming to be able to cure all diseases by the potency of cocaine. He gave it indiscriminately to all his patients. He gave it to obstetric cases and to syphilitic cases. He gave it to his wife, his three children, and his mother. He was formerly a modest man of science; he became bold and unscientific in his method, went about engaging in lawsuits, carrying a pistol and frequently brandishing it in public places, threatening vengeance upon all who dared to doubt the correctness of his various extravagant statements—a perfect terror in his neighborhood. He had been a very devout member of the Roman Catholic Church, but the priest of that church could now do nothing towards restraining his wild impetuosity. He neglected his practice, and by his manner alienated those whom he did not neglect, so that very soon he lost it. Piece by piece his horse, his buggy, and his furniture disappeared, until his family was reduced to poverty. My repeated efforts to persuade him to stop the use of the drug were unsuccessful; indeed, simply resulted in making me the recipient of his wildest denunciations and of his severest threatenings. Several physicians and druggists who made attempts to restrain him met with an equally positive rebuff. The same general deterioration as before noticed was manifest in his case: extreme pallor and dryness of skin, great emaciation, loss of appetite and no desire for sleep, so that for at least one week he did not assume the recumbent position.

He continued to go from bad to worse until his friends thought it best to restrain him. In pursuance with this object, Dr. F. L. Wadsworth and I appeared before the county court, and advised his removal to the Washingtonian Home. Here the cocaine was gradually withdrawn, but his mental extravagance continued unabated. He left this institution clandestinely, and is now supposed to be in Canada.

To sum up:

1. Cocaine in small or moderate doses is a cerebral stimulant, but produces derangement of the digestive and assimilative functions, and diminishes the elimination of waste.

2. The use of cocaine in the alcoholic and opium inebriates is not satisfactory; while it is a more or less perfect substitute, yet its use is attended with greater danger than alcohol or opium.

3. The use of cocaine in mental depression, if we carefully guard against the depressing effects of the drug upon digestion and assimilation, will often give better results than any drug hitherto used.

4. The use of cocaine in neurasthenia is a valuable addition to the treatment.

5. The drug, if administered in large doses persistently, causes a very marked deterioration of the central nervous system, producing a profound cerebral neurasthenia, and may produce such a malnutrition of the cerebrum as to develop insanity.

6. Cocaine, occasionally, in doses heretofore regarded as small, produces alarming depression of the central nervous system.

COCAINE AND HAY-FEVER.

BY J. E. SHADLE, M. D.,

Of Shenandoah, Pa.

The remarks of Prof. Da Costa before the College of Physicians on the treatment of hay-fever by cocaine prompt me to report a case which came under my observation over two years ago, and was at last successfully treated by a local application of a four per cent. solution of cocaine:

During the month of August, 1884, John B., eighteen years of age, paper-carrier by occupation, presented himself at my office suffering from an affection of the head and nasal passages which I diagnosed hay-fever.

There were present frequent seizures of sneezing, pain in the eye-balls, excessive lachrymation, frontal headache, and a feeling of constriction throughout both nasal passages.

I prescribed for him liberal doses of iodide of potassium for an indefinite time. Seeing that no good arose from a regular use of this remedy, a change was made from it to increasing doses of Fowler's solution of arsenic, accompanied by posterior nasal injections of a carbolized solution of iodine. This mode of treatment was continued sufficiently long to give it a fair trial. The result was unsatisfactory, and my patient remained unrelieved until a few October frosts came and removed the difficulty.

From this time on he enjoyed good health until August, 1885, when he was seized again by the same annoying trouble. His suffering this time seemed greater than the year before; and as the distress was almost unbearable, he again applied for treatment with the hope that something might be done to relieve him.

Knowing that in the previous year all that had been prescribed for him failed in producing the least benefit, I was considerably perplexed in conceiving as to what should be done on this occasion for the young man, in order to afford him relief.

After a little research for a remedy, cocaine presented itself to my mind as being worthy of trial; whereupon I instilled into each nasal passage, with a medicine-dropper, about ten drops of a four per cent. solution of Squibb's cocaine. In ten or fifteen minutes after the application the patient said he felt some relief. Upon his departure from my office I asked him to report the result in two days. He did so, and he was overjoyed with what the new remedy had done for him. In fact, all the formidable symptoms of the disease were so much ameliorated that it seemed needless to pursue the treatment any further.

Two more instillations four days apart were made, after which the treatment ended, and my patient continued perfectly free from the attacks.

He was so well pleased that he expressed a desire to be similarly treated next year, should the disease then occur.

Two points are to be noted in this case:

1. The disease did not yield to the usual remedies prescribed in hay-fever.

2. Cocaine, locally applied, furnished immediate and permanent relief.

—"Let us pursue the subject a little further," said the medical students at the bedside of a dying patient. So the next night they went out and stole the body from the cemetery.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Dr. Theophilus Parvin.

Diagnosis of Pregnancy.

Those of you, gentlemen, who have read "Hume's History of England," will remember the peculiar case of Queen Mary, who was supposed to have conceived by her cousin Philip. She claimed that she was conscious of the movements of the child, and she was sure it would be a boy. Prayers were offered up that he would prove a strong, wise, and virtuous man. She was examined by eminent physicians, and they were of the same opinion. Time passed, and no child appeared, and subsequently "Bloody Queen Mary" died with abdominal dropsy.

Another famous case of feigned pregnancy was that of Johanna Southgate, who claimed that at the age of seventy she was pregnant with a "new Jesus," and she endeavored to rally about her those who saw in this miraculous event divine interposition, for the purpose of forming a new religion. She was examined by doctors, who thought they felt the movements of the fœtus, and her abdomen was enlarged. It all turned out to be a myth, for the old woman had a fatty tumor. This was before the recognition of the fœtal heart-sounds, which constitute for us now a positive means of diagnosis.

It was in 1818 or 1819 that the first observation was made on the fœtal heart-sounds, and shortly afterwards attention was called to the uterine souffle, which has, until recently, been erroneously called the *placental* souffle. That this sound is really produced in the uterus and not in the placenta is now abundantly demonstrated. I must here caution you about a source of error very common in observations: when a man looks for a certain thing, he generally finds it; when we start out to demonstrate a fact from preconceived theory, we can usually find sufficient evidence to make a *prima facie* case; hence facts, or supposed facts, arising from theories seldom amount to much, while the greatest discoveries in science have usually been the results of accidents—that is to say, they were not being looked for when they were found. Thus it was with the souffle and the fœtal heart-sounds; those who found them, were not specially searching for them, but were making other observations on abdominal auscultation, when these unlooked-for facts were forced upon their notice. If

you look at the sun through a frosty window-pane on these cold, winter mornings, you might imagine the universe to be made of gold; the power of imagination in making seemingly real that which we wish to be so, is very great, hence you must always make allowances for this source of error. As evidence of how slight and accidental are oftimes the suggestions of great facts, let us turn to vesper-time some centuries back, in the beautiful cathedral of Pisa, where during the hypnotic singing of psalms, a man sat, thinking of other matters than those of religion, when his drowsy attention was riveted to the swinging to and fro of the sanctuary lamp, and from this slight incident was suggested to the fertile mind of Galileo the theory of the pendulum. Again, let us remember how Newton, on a warm summer's day, lay down beneath a tree to doze, when an apple, striking him in the face, suggested to his mind the great fact of gravitation. Still further, let us ever bear in mind how thoroughly accidental was Jenner's immortal discovery.

To go back to our subject, we may have morning sickness, uterine enlargement (real or apparent), changes in the breasts, all due to causes other than pregnancy, but it is simply impossible for any other cause to give us the fœtal heart-sounds; nothing under heaven can simulate this condition; when we have positively detected them, we can formulate a decisive verdict that will never be overruled. It is ordinarily easy to discover these sounds, but not invariably so; and it is not at all an easy matter to detect the shades of difference in them, that are frequently of considerable importance. In his great work on auscultation, published in 1819, the second edition of which appeared in 1826, Laennec tells us that abdominal auscultation is much more difficult than that of the chest, and I assure you that it is so. It is difficult to diagnose the position of the child, but by practice you can do this, and it will sometimes tell you when to use the forceps.

When we auscult the abdomen of a pregnant woman, we will hear four sounds: 1. The uterine souffle; 2. The fœtal heart-sounds; 3. The fœtal circulation; and, 4. The movements of the child. The uterine souffle you will commence to hear about the close of the third month, and it will grow gradually louder until the seventh or eighth month, from which time on it retains the same degree of intensity. I trust that no one will speak of this as a *placental* souffle, though in a recent edition, a distinguished teacher does so call it, and his French reviewer says that "we never hear of a placental souffle in France any more," and I trust we will hear no more of it in the United States. You will surely realize that it cannot be placental, when I tell you that we can hear it for some time after the removal of the placenta, and also in some cases where there is no pregnancy. This sound will give no indication, as some supposed, to the site of attachment of the placenta. Some years ago I read in the *Practitioner* an article by an Irish physician, who claimed that when the sound was heard near the right oviduct, it was evidence that the fecundated ovule had come from the right ovary, and *vice versa;* and he endeavored in this way to determine the sex of the child, claiming that male germs come from one ovary and female from the other. The answer to this statement it to be found in the fact that women who have had one ovary removed, have subsequently borne children of either sex. Some have contended that the souffle was caused by pressure on the aorta and the primitive iliacs, but there is no shock in this souffle. It is an undulatory sound; like a wave it ascends, there is a height and it descends, there is a pause, and this process is repeated. Sometimes the sound is sibilant, sometimes sonorous. I think the true theory of its causation is founded upon the passage of the blood through the uterine sinuses. We know that when a fluid passing through a canal of uniform dimensions, passes suddenly into a canal of greater dimensions, or into a number of canals whose united dimension is greater than that of the original channel, it will produce a sound. For instance, the water in a canal "lock" is quiet and still, but when it is let out into the canal beyond, there is a splashing, gurgling sound; "still water runs deep," but when it broadens out, we have a sound. The blood-vessels leading to the womb are much enlarged in pregnancy, but the vessels of the womb itself are still much more enlarged, in fact, the veins become so distended that their coats are almost lost, and they really form sinuses in the body of the organ. The souffle is heard most distinctly at the sides of the uterus.

Now, an important question arises: should we resort to immediate or mediate auscultation; that is, should we use a stethoscope? I say, undoubtedly, yes. I consider that it is indelicate, aye, almost indecent, to apply the ear directly to the abdomen; while in labor, the cry of pain shrouds the cry of shame. While, as Prof. Jackson used to say, "the

martyrdom of maternity" drives every other thought from the woman's mind, it is not so beforehand; and a delicate and refined lady would not, and ought not to be expected to, submit to the ear on the abdomen; but gentlemen, no matter whether the woman be *delicate* and *refined* or not, no matter if she is one of the large army of unfortunates, you should always remember that you are gentlemen, and treat the patient with becoming delicacy. Always remember the story of the railroad conductor out in Iowa, who was very polite and attentive to an old lady; when it came time for her to leave the train, he lifted off her bundles, and paid her every attention. Said one lady to another (loud enough to be overheard by the conductor) "She must be his mother." "No, madam," replied the conductor, "but she is somebody else's mother." Remember that your patient is *somebody else's* mother, sister, or wife, and do not forget the golden rule, to do unto others as you would have them do unto you.

Remember, that woman's salvation is in her modesty, and as you value your good name, do nothing to break it down. Observe the most careful precautions in your intercourse with your female patients. Do not shock or break down this beautiful barrier of modesty, and let this caution be doubly enforced in your intercourse with fallen women, who are usually more sinned against than sinning. Another reason for using the stethoscope is that you cannot bury the ear in the flanks without causing pressure that will prove annoying both to the patient and the doctor. Still further, in this constrained position of the neck, the muscles, and the beard against the abdomen, will cause misleading sounds.

Before ausculting, the bowels and bladder should be emptied, so that the abdomen may be thoroughly relaxed, and you should always auscult in the intervals of pain if performing this operation during labor. The room must be quiet (which is not the case in this room, for some of the class seem to forget that my clinic, which commences at nine o'clock, like time and tide, waits for no man). The ordinary expression of the greatest quietude is that you could hear a pin fall; but in her description of a wedding (that did not take place), Mrs. Browning furnishes us with a new and expressive phrase, when she says that the church was so quiet that "in the silence of that vast throng, a babe could be heard sucking in the most distant aisle." Such is the quietude necessary for proper auscultation.

Delicacy dictates that a covering should intervene between the abdomen and the stethoscope, and I am quite sure that we can hear just as well through a thin, unstarched chemise. The instrument must held *in situ*, otherwise it will slip, especially from the redundant abdomen of a multipara. Remember that as the uterus enlarges and rises, it does so in the axis of the inlet, and the stethoscope must be applied perpendicularly to the fundus during the earlier months; later it can be applied at any point. Let us draw a line from the ensiform cartilage to the symphisis pubis, and cross this by a line intersecting it at the umbilicus, then drawing a line from the umbilicus to the anterior superior spinous process of the ileum, we will have the fœtal heart-sounds about the middle of this line. Remember that ninety-five per cent. of labors offer the vertex presentation, and that in fifteen out of twenty of these it is the left occipito-anterior, when the sounds will be heard on the left at the middle of this imaginary line; in the other five it will be heard on the right. The average beat is 140 per minute, and the sound resembles that of a watch under the pillow, a *tic-tac*, *tic-tac*, but remember that the interval between the *tac* and the *tic* is twice as long as that between the *tic* and the *tac*. I do not credit the claims as to the prediction of sex from the rate of pulsation. I have a friend out in Louisville who claims that when the pulse is under one hundred and thirty-five it is a boy, and when over that a girl; you know the poet tells us that the pulse beats our funeral march to the grave, and it would seem from this that women beat faster, commencing even in utero; it is a fact that in many cases my friend has happened to be correct in his forecasts, but I do not attach any importance to these signs. The sounds will vary in distinctness, in force, and in frequency, so that I might say that to be proficient, it will not do to merely hear the sounds, but we must tell all about them. I listen and listen to this supposedly pregnant woman's abdomen, but I cannot hear the sounds, though my resident says she has heard them. Babies, even in the uterus, sometimes go to sleep, and take exercise, etc.; they are very fond of kicking, which might account for the tendency to foot-ball in later life. There is some obscurity in this case, and it demonstrates the necessity of serving an apprenticeship to fœtal auscultation. I do not believe in early success, and think it a good thing for a doctor to meet with downfalls, which only serve to gird him with renewed strength. We remember the fable of the giants who were worsted in

battle; falling to mother earth, they acquired renewed vigor, and proved victorious.

So with us, we require to be sometimes thrown down, that we may gain new strength from our disappointments. There was a countryman one time, who reading the sign in a store-window, "helps to read," went in to buy one. The "helps" were spectacles, and the storekeeper tried several pair, but the rural gentleman would invariably answer that he could read no better. Finally, he was asked if he knew how to read; "No, of course not," said the man, "I supposed what you were selling would help me to read." So with fœtal auscultation, you must by practice learn the principles, before it will help you to elucidate problems.

In some cases you will have a sensitive abdomen and an irritable uterus, when it will be necessary to desist; and in such cases the irritability may be allayed by an opiate, preferably a half teaspoonful of laudanum in half a cup of water by injection. Now I am going to ask this student to count the fœtal heart-sounds, for while we are all supposed to be *accountable* beings, yet it is but rarely that any two men will make the same count, even of the radial pulse. Some men have advocated placing the woman in a quadrupetal position when ausculting, as it would bring the uterus nearest to the abdomen, but I would not envy the position of a doctor with his patient in such a position. The uterine souffle also varies in location and intensity; sometimes it may be heard all over, at others only in spots; and it is also sometimes heard in fibroid tumors, and in some cases of ovarian tumors, though it is very exceptional in the latter; and it may be heard when the fœtus is dead. So, taking all in all, the heart-sounds will prove the diagnostic point par excellence. There is what we term "painless contraction" of the uterus, by which the circulation is aided in the uterine sinuses, and which will serve as an aid to diagnosis; it also serves to determine the position of the fœtus.

In some rare cases the fœtal heart-sounds may not be heard throughout the whole of pregnancy. If you hear them, you can be sure of pregnancy, but if you do not hear them, you cannot be absolutely sure of its non-existence. If you have surely heard it, and later fail to detect it, you can be sure the fœtus is dead. These sounds will also aid you to form an opinion as to the health of the fœtus. If it is sick, the sounds will be irregular, very frequent, or very slow. A diagnosis of multiple pregnancy can be better made by auscultation than in any other way. It is of the utmost importance that you should study this matter carefully, for a man might as well cut off his right arm as make a mistake. Nearly every city has its tradition of a case of overlooked pregnancy where ovariotomy has been performed. We may confound the maternal with the fœtal circulation, if we are not careful to feel the mother's pulse and note the discrepancy in the two. We are also liable to confound our own circulation, especially if the position assumed be constrained. Do not trust to a single examination, but repeat it.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. William Thomson.

Iridectomy.

I will show you, gentlemen, two cases upon whom I operated last week, performing Graefe's operation, which is the one that I prefer. Cocaine was used, and both patients declare that the operation was painless, though I think that some pain must be experienced when the iris is cut off, because I do not believe that the cocaine is sufficiently absorbed to deaden the sensibility within. In one of these cases we had a very severe experience, for notwithstanding the fact that the matter was fully explained to the man, he seemed to dread the operation, and while endeavoring to make the primary incision he rolled up his eye half a dozen times; finally the eye had to be held in position with forceps, and there was so much tension that the knife came out too soon and, as there was difficulty in catching the iris, I passed a wire loop down behind it, and removed the whole crystalline lens with its capsule, after which there was a slight escape of vitreous humor, the first time this has occurred in this amphitheatre in years. The eye is now practically well; I never saw a case where there was so little irritation. This is one of the peculiarities of surgery. The surgeon will sometimes tell you that he has removed a very small stone from the bladder, and the after-effects have been very serious, while in another case where the stone has been large and has required great manipulation and crushing, the sequelæ have been favorable from the start; so you cannot always predicate results from the severity of the operation.

Conjunctivitis.

Of the several forms of conjunctivitis the simplest is the traumatic, as that caused by some foreign body or some irritant in the eye. There is a gritty, sandy feeling, as it

were, with some watering and redness; next in severity comes catarrhal conjunctivitis, though I am not quite sure that that this is a correct name for it, because it does not possess the characteristics of catarrh elsewhere. As an illustration of traumatic conjunctivitis, look at the eye of one who has had some cigarette smoke blown into it. If catarrhal conjunctivitis lasts long enough, there may be some exudation and thickening of the mucous membrane. Here is a woman from the country who, after exposure to cold last Tuesday (this is Friday), commenced to have lachrymation, a sandy sensation in the eyes, and found the lids glued together in the morning. The eyes look as though they were varnished, but there was no photophobia; in more severe cases, when the cornea is involved, intolerance of light will be marked. The mucous membrane is very red, and the inner caruncles are much swollen. I recognize this as a case of catarrhal conjunctivitis from the absence of acute pain and photophia. If there was pain in the head, extending down the sides of the nose, we would know that there was more severe trouble; the eye might look as it does here, yet there be a severe iritis impending. Now, I cause this woman to close one eye, and shading the other from the light the pupil dilates, when exposed again to the light it contracts; the same is true of the other eye; therefore, I know that since the iris responds so well it cannot be inflamed; this is a practical point for you. Another point in favor of my diagnosis is that both eyes are affected; if only one were attacked I would examine more critically for some deeper trouble. Now, I tell the woman to close her eyes and I palpate each, to see if there is any undue tension, for, if there be, it would cause us to look for glaucoma. The only treatment that this case has received has consisted in the application of salt water to the lids. It is of the utmost importance to first make a correct diagnosis before instituting treatment; and having decided the nature of the trouble in this case, I will order a weak wash of alum (gr. ii.–f.℥j.), or in some cases boracic acid or borate of soda (gr. v.–f.℥j). Into a pint of warm water, she will put a small salt-cellar full of salt and bathe the eyes therewith, using the alum wash every two hours, You must instruct your patients to hold the head back, drop the liquid in the corner of the eye, with the eye closed, then draw the upper lid up and the lower lid down, that it may be well applied to every part. As a rule, it will take about ten days to cure such a case. The lids should be smeared at night with cold cream, vaseline, or cosmoline, to keep them from sticking together. We will direct this woman to come back at once if her eyes get any worse, for we may have a serious time here before they get well.

Then we have purulent conjunctivitis, which is a most serious affair; the $\frac{1}{1000}$ part of a drop of gonorrhœal pus applied to the eye would cause it. It is characterized by enormous swelling, the eyes are closed, the lids project, and if we separate them there will flow out, maybe, half a drachm of a greenish pus. The all-important matter in such cases is to keep the infecting material from the other eye; it must be hermetically sealed, for the disease is horribly contagious. An ingenious plan to accomplish this is to cover the well eye with a watch crystal and fasten all around its sides with adhesive plaster; this will absolutely protect, and will, at the same time, allow of vision. The inflammation may be so violent in these cases as to strangle the blood vessels and cause sphacelation of the cornea. The condition is an awful one. Here is a young man who had a piece of iron in his eye; whether this caused sympathetic inflammation of the other eye or whether he contracted purulent ophthalmia from the hands of an attendant, I am not prepared to say; but he had the worst eyes I have ever seen, and has been left totally blind. In some of these cases we will have staphyloma of the cornea, there will be a bulging outwards from the pressure of the iris on the thin and weakened cornea. The treatment in such cases must be energetic; we must at once subdue the inflammation, applying ice constantly, night and day, and using every little while a five grain to the ounce solution of alum, everting the lids and painting them with a twenty grain to the ounce solution of nitrate of silver. A parturient woman, with a leucorrhœal or other discharge, even of a non-specific nature, may give to her child a purulent conjunctivitis that will relegate it to the list of the incurably blind.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

Meeting, January 4, 1886.

Discussion on Cocaine. (*See page* 132.)

Dr. E. L. Holmes opened the discussion by saying that the South American Indians ate large quantities of the coca leaf, without injury.

Dr. D. R. Brower said that in the early history of Peru the Catholic Church authorities sought to stop the use of coca in that way, because of its deleterious effects upon the people. But it was impossible to do it; they used it clandestinely, and the prohibition was withdrawn. Dr. Brower said that used in that way the result was a similar condition of mental deterioration to that mentioned in the paper; while these people were capable, under its influence, of performing muscular efforts in climbing the hills and mountains of that country, they were a puny, sallow, emaciated people, with intellectual capacity very little above the brute creation.

Dr. E. L. Holmes said that his experience had been wholly in connection with local applications on the eye. He had seen one case, in which he had placed cocaine in both eyes for an operation, in which it was followed by considerable depression and nausea through the night, but no alarming symptoms. He had twice used it in his office for strabismus, placing a not unusual quantity in the eye, where the patient felt sick and almost slipped out of the chair, and the operation was performed with the patient lying on the floor, but he suspected it to be a fit of fainting at sight of the instruments. He had found from experience that very minute doses will be absorbed, but had never seen the slightest influence from the amount which is usually given in the eye. It is exceedingly satisfactory in performing operations and in removing little motes and pieces of iron or steel lodged in the cornea.

Dr. C. W. Earle said it appeared to him that when Dr. B. was in the Washingtonian Home he got along with a very small amount of the drug, very much less than Dr. Earle had anticipated it would be possible for him to get along with. Dr. B. informed him that he had been in the habit of taking from 15 to 18 grains a day. After he went into the home, the first three days he took less than grs. iij, and after that time did not take any. He regained his appetite very well, and appeared to improve in every respect up to the time that his wife and brother or brother-in-law came from Canada to visit him; then he was seized with an idea that he must go home, or at least to Canada, and from that time he was uneasy and did not do well. Dr. Earle said that it seemed to him that there had been more said in regard to the use of cocaine than there was any use in saying. While Dr. B., was at the Home he was not unlike an ordinary opium eater. The depression which followed withdrawal was somewhat similar, although there were none of the symptoms of dizziness, or nausea and sneezing, which are usually present after the withdrawal of opium.

Dr. Sarah Hackett Stevenson said that she was surprised at the deleterious effects found by Dr. Brower from the use of cocaine in hay fever. She had had a number of cases in which it was used, without any of the symptoms mentioned in the paper. She used a 4 per cent. solution, applying with a camel's-hair brush, or simply by snuffing. Dr. Stevenson said she had used cocaine a great deal hypodermically in surgical operations, with good effect so far as anæsthesia was concerned.

Dr. F. W. Coleman said there are two lines of practice in treating the narcotic habit; to cut a man off from his drug completely, at once, or to taper him off. He believed in depriving him of the drug at once. If he found a man poisoned, he would not add another dose, but stop it immediately. He knew nothing practically of the internal use of cocaine, but was surprised at the grave effect mentioned by Dr. Brower. Cohn-Mueller asserts that he kills a frog with four-tenths of a grain, but to human patients he gave indiscriminately five grains, and it produced no perceptible ill effect. Locally, Dr. Coleman had had some experience with the drug; and there is this point about its immediate effect, it relieves pain in acute otitis, but it is a grave question whether it does not prolong the case, and while it relieves pain it is doubtful if it is better than hot water or other remedies. In its application to the eye there was not this objection; it produces anæsthesia and allows almost any operation to be performed without pain; it does not prolong congestion, and gives permanent relief.

Dr. D. W. Graham said that he noticed Dr. Brower quoted a case reported by Dr. Burchard in the *Medical Record*, in which a patient sustained a loss of consciousness and stoppage of the pulse after an injection of four-fifths of a grain of cocaine. Dr. Graham doubted very much whether the bad effects were due to cocaine; we get the same effect in many patients by injecting water, or by showing them the hypodermic syringe, and he thought it probable that it was simply a fainting fit. There was nothing in the report that would lead to any other conclusion, except that Dr. Burchard says it was the result of the injection of cocaine. Dr. Graham doubted the conclusion, and thought it unreliable.

Dr. F. M. Weller said he had had some experience in the use both of cocaine and the

fluid extract of coca. He had never used such large doses as those mentioned, but had seen that very large doses of the drug would produce unpleasant symptoms about the head, dull heavy headache, something like doses of other narcotics. Hypodermically he had used as much as five grains at one time without any unpleasant effects whatever. He was inclined to think that the real difficulty in some of these cases was that some other circumstance was overlooked. It seemed to him that some idiosyncrasy might exist that would make one peculiarly susceptible to this kind of narcotic, and it would hardly be reasonable to charge it all to cocaine. His reading of the history of the use of the drug in South America, where it originated, led him to think that it could be used a long time without injury. He thought one lesson is to be learned from the paper, viz., that no drug should be continued beyond the time of its necessity. This principle laid down and strictly adhered to, the patient would never suffer from the deleterious use of any drug.

Dr. D. R. Brower in closing the discussion, said that Dr. B. bought cocaine wherever he could get it, and he did not know what preparation he used. The other physician mentioned in the paper used Merck's cocaine altogether. He used it for hay fever, and took five grains by inhalation every day for ten days. Dr. Brower said that he did not suppose that such disastrous effects, as occurred in these cases and others, would result unless there was some weakness of the nervous system; he thought possibly a person perfectly robust and with a well-governed nervous organization could take cocaine with impunity, but a person with a nervous temperament could not use this drug continuously without some such results following. Dr. Brower said his plan of treatment was that of gradual withdrawal, as well with opium and chloral as with cocaine. This plan could be followed with less inconvenience to the patient. Dr. Brower said he was well aware that cocaine was one of the most valuable additions to the therapeutics of hay fever; it had been administered in perhaps thousands of cases in Chicago, and with few disastrous effects. As to the case reported by Dr. Burchard, the doctor reported it as a case resulting from hypodermic injection, and it struck Dr. Brower as being a reasonable result in a very susceptible individual, but it might be that the man had a fainting fit. The case was reported in the *Med. Record* of Dec. 5, 1885; it impressed Dr. Brower as being undoubtedly a case of cocaine poisoning.

After the reading of a paper entitled "Opium Smoking," by Dr. C. W. Earle, and one entitled "Hygienic Clothing," by Dr. L. L. McArthur, on which there was no discussion, the Society adjourned.

CINCINNATI ACADEMY OF MEDICINE.

Stated meeting, November 28.

President, Samuel Nickles, M. D.

Dr. J. H. Taite, late obstetrician to the Cincinnati Hospital, reported the following, which he believed to be

A Case of Superfœtation.

A healthy American woman, æt. 28, in her second gestation, missed her menses November 21, 1884. A few days later she complained of nausea and occasional vomiting. She said that her feelings were just like those experienced during her first pregnancy. Two hundred and eighty days from the disappearance of her menses, she felt the premonitory pains of labor. These pains she said were in no respect different from those she had before when labor really began. These pains recurred again, at intervals, until real labor took place. This occurred October 15, 1885, 326 days after the disappearance of the menses. The labor went on normally, except that the pains were rather slow. The woman was in labor 30 hours, and gave birth to a well-developed female child. It was apparently at full term, and would weigh 7½ pounds. The placenta to which the cord was attached came away in twenty minutes after the birth of the child. The placenta and membranes were in every respect normal, except that they were a little under size. The delivery occurred between 9 and 10 at night. The doctor visited the patient the next day between 9 and 10 a. m. He found that something like a piece of membrane with the placenta attached was lying at the orifice of the vagina. On endeavoring to remove this the fingers were passed into the vagina, and it was found that membranes and cord were present. To these another placenta was attached, which was the size of the first. This was fresh, and in every respect resembled a normal placenta, with the exception that the cord had a diameter no greater than that of two or three broom-straws. No portion of a fœtus was found. This may have escaped with the clots which came away with the first placenta or immediately after, but if so, they were not discovered. As is his habit, contrary to the teachings of most authorities,

in removing the placenta he not only made pressure on the fundus, but also traction on the cord. In the lower animals estruation frequently occurs coincident with fecundation. This leads us to believe, reasoning from analogy, that it may occur in the human female. Gestation and ovulation can go on in the bifurcated uterus, why not in the single? He referred to the records of the English Peerage, where the birth of each child is carefully recorded, and which records show several instances of superfœtation. He quoted the case of Tyler Smith, also one which occurred in Strassburg. In this case a woman was attended by a midwife, and delivered of one child at term. She said to the midwife that she thought there was another child in the womb. She was brought before the surgeon of the barracks, who examined her and told her that she was right. A second child was born 140 days after the first.

Dr. J. T. Whittaker, in the discussion which followed, said we must have a clear understanding of the difference between superfœtation and super-fecundation. The former means the impregnation of a woman after a pregnancy has advanced to a considerable period. Super-fecundation is the impregnation of more than one ovule at or near the same time. Super fœtation is a physiological impossibility. The evidence for superfœtation is valueless, so far as the specimen presented here to-night is concerned. It is claimed that menstruation occurs during pregnancy—not every hemorrhage from the uterus is a menstruation. True menstruation does not occur during pregnancy. True menstruation is physiological; metrorrhagia is pathological. One child at full term may weigh five, another ten pounds at full term. Twins vary greatly in size. Is it at all surprising that twins in a bilobed uterus should show difference in development? This claim of superfœtation is a most superannuated doctrine. The cases reported by the speaker of the evening are all from ancient literature. Ancient literature abounds in marvels. Not one of these cases will bear criticism. Gestation precludes ovulation as a law. Lactation only precludes it as a probability. Proof puts the whole question beyond a doubt. There is no doubt but that conception requires an egg. If any one will find proof positive of pregnancy in a woman, he must find a ruptured follicle, and in a fresh case the corpus nigra, subsequently a corpus lutea. A fresh corpus nigra or corpus lutea has never yet been demonstrated, except the one which fills the uterus. Thus, superfœtation ceases to be a fact, and becomes a myth.

Dr. T. A. Reamy cited the recent case of Dalton as not ancient. The appearance of the corpus lutea, he said, is not conclusive evidence of pregnancy. Dalton cites a case where a woman never ovulated, yet conceived. I have the notes and addresses of twenty patients who never menstruated, yet conceived. The classical article and reports of cases by Dr. Bonnar, of Cupar, in the *Edinburgh Medical Journal*, January, 1865, and many other facts, are a downfall to the statements that ovulation cannot occur during pregnancy. Some women may conceive from menstruation to menstruation, others only a few days before or after this time. As to the specimen presented, he desired to say that it must be a part of the placenta removed the day previously. He then reported two cases of superfœtation from the literature.

Dr. Taite, in closing, gave his reasons for still believing the second placenta removed to be entirely different from the other. But two of the cases he had cited antedated this century. The others were subsequent to 1840. He was glad of the fact that his case had stood the test of critical examination.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, November 27th, 1885.

The Vice-President, Dr. John B. Roberts, in the chair.

Discussion on Typhoid Fever (*See page* 98).

Dr. Edward T. Bruen said that the fever was an incident, or feature, of the general process of enteric fever. Since we cannot limit the course of the disease, it is well not to treat the symptom of rise of temperature, even when as high as 104° or 105° F., unless mischievous brain symptoms arise, or other direct evidence that the elevation of temperature is decidedly unfavorable to the comfort of the patient. The cold water treatment is the most efficient antipyretic agent, but it may induce such exhaustion of the patient that it does more harm than good. In August he supervised the treatment of sixteen cases of typhoid fever, many of them in the University Hospital, and in *five* of these cold water was used to reduce temperature, but in only *two* of them was it followed by a good result—in the others the treatment produced decided discomfort.

He does not habitually employ *antipyrin* as an antipyretic, because he does not habitually aim at reduction of temperature. But his experience with antipyrin went to show

that this agent will reduce temperature more quickly than quinia, and without unpleasant consequences. The drug is particularly useful when the temperature lingers above normal in the closing stages of enteric fever, or at the close of a relapse. The reduction of temperature may continue several days after the use of antipyrin. The dose he employed was *ten* grains every hour, in compressed pills—sometimes using forty grains. Antipyrin can, however, be given in solution, but has an unpleasant taste.

In reference to *phlebitis*, he objects to the use of mercurial ointment, because it is difficult to remove it without causing much suffering to the patient, and because constitutional symptoms may follow, especially under certain plans of internal treatment which may be carried on conjointly. Blistering is a painful mode of treatment, and the good effects are not marked. The use of hot applications, especially vinegar or laudanum and hot water, and sometimes hot lead-water, are very soothing and useful.

In the *prognosis* of typhoid, the state of the *heart* is a most reliable guide, and he believes in an early supporting treatment. Perhaps all will admit that the early use of alcohol is very serviceable, but at all events the diet, if limited, may be very nourishing. Beef-tea he seldom uses unless as a laxative, but if milk is badly digested, there can be no objection to the use of custards, plain rice pudding, milk-toast. In this way the strength of the patient is preserved, though, of course, the amount of food given must be within the reach of the powers of digestion.

Dr. Edward R. Stone said that he had had good results from quinia per rectum. He had seen one case of convulsions in typhoid fever, but it was rather the convulsions of childhood ushering in the disease in a child æt. 8 years, who had an unstable nervous system. He had seen one case of prolonged cerebral inactivity, in a boy of 14 years, after a long and prostrating course of typhoid fever. It was a long time before he could read, but after two or three months his physical condition improved, and with it his mental condition. He thinks that patients are rather *over-fed* than *under-fed*. It is necessary to lay down directions in regard to the *amount* and *time* of feeding.

Dr. L. Brewer Hall said that he had sometimes found small thromboses in the veins of the eye and hemorrhage into the retina after typhoid fever; and he questioned if there might not be the same condition in the vessels of the cerebrum in these cases of cerebral inactivity.

Dr. Henry Beates said that he was especially desirous of giving emphasis to a point made by the author of the paper in regard to the administration of quinia, and that is its use per rectum, whereby its local irritant effects are avoided, and the undoubted serious mischief almost necessarily following its administration by the mouth are also avoided. In reference to the successful and unsuccessful use of antipyrin, in a very limited experience, he has been forcibly impressed with two clinical facts, which, before being stated, will be premised by the teaching of Prof. H. C. Wood regarding fever: 1. *Pyrexia is due to* —heat production being normal, and heat elimination subnormal; 2. heat production being *above* normal, and its elimination normal. Now take two instances of high pyrexial typhoid: they each, for three or four consecutive evenings, possess a temperature of 104.5°, but the one does not emaciate as the other, neither does he, notwithstanding that the temperatures are identical, evince that serious inroad of his vital forces indicative of approaching dissolution. Indeed, were it not for the thermometric observation, we should be ignorant of the high degree of pyrexia. He believes that these two pictures indicate the proper use of antipyrin. Where the temperature is high and emaciation not correspondingly marked, antipyrin will successfully, *temporarily*, reduce it; but where pyrexia is high, and emaciation great, it is valueless. The *one* fever point is maintained, principally, by *nervous phenomena;* the *other* by *active tissue change.*

Dr. John B. Roberts said that he had seen ulceration of the cornea, and of cellular tissue, as a result of typhoid fever.

Dr. Walker, in closing the discussion, said he believed in *free* feeding in typhoid fever, but not in *over*-feeding.

In a case running a mild course, without severe intestinal symptoms, he permits the use of soft-boiled or poached eggs, or egg-custard with milk toast, at times, to vary the monotony of the milk diet; but where the milk agrees he considers it a sufficient and superior diet for any case, in from three to four pints daily.

As for the prognostic significance of complications, no doubt they add to the gravity of the case whenever occurring, and require greater care on the part of physician and attendant than an uncomplicated case; but the *exact* influence, in increasing percentage of deaths, was not known to him. As regards the idea thrown out by Dr. Hall, that on account of extravasations and ecchymoses in the retina, after typhoid fever, it might

be inferred that similar changes exist in the cerebral tissue, inducing the mental hebetude, etc., he would simply say that, inasmuch as the eye changes induced more or less permanent defect in many cases, and whereas the mental hebetude was almost invariably without permanency, and cerebration was thoroughly re-established, he thought we have sufficient indication that central extravasations and ecchymoses were extremely uncommon as a cause of imperfect cerebration.

Editorial Department.

Periscope.

An Operation for Pruritus Vulvæ.

Prof. O. Küstner, of Jena, in the *Gynacol. Central. Blatt.*, xi., 1885, discusses the above subject.

In the year 1884 Schroeder published a lecture on the Operation for Pruritus Vulvæ. He had operated on four patients. He could enlarge this number very much if he would add to it those on whom he had operated for carcinoma of the vulva.

In regard to the ætiological factors in the disease, the author is of the opinion that it occurs quite seldom from a primary neurosis, and more frequently from an irritation of the part, through which an abnormal sensitiveness of the vulvar mucous membrane is occasioned. This sensitiveness comes mostly from catarrhal secretion of the uterus or vagina, which continually moistens the vulva. Only in the commencement of the condition can it be cured through the removal of the catarrhal condition. If the morbid sensitiveness is of old standing, it has become of such a high grade that it does not subside when the diseased condition of the uterus or vagina is removed. The disease is made worse through the rubbing and scratching. Then occur miliary formations (two cases reported by the author), or sclerosis of the mucous membrane (three cases by Schroeder), eczema, eruptions herpetic in character, and similar affections.

The first case in which the author did the operation was a maiden, how old is not stated, who had suffered from a uterine catarrh and pruritus vulvæ. The catarrh was improved, but the pruritus remained. Its position was on two symmetrical places situated between the nymphæ and hymen. These parts were thickly studded with miliary bodies, as is often found to be the case where there is no pruritus. The author removed two lips of the mucous membrane, filled with these miliary bodies, and united each of the wounds by means of a suture. Recovery followed. The pruritus was cured, and has not yet returned, after four years.

Case 2 was an unmarried woman, æt. 36, who had earlier been addicted to masturbation. She suffered from uterine catarrh, from neuralgias of all kinds, and from pruritus. Here also were numerous miliary bodies found in the diseased place. The operation was made on the posterior part of the labia minora. Recovery. For a short time the pruritus was not entirely removed, but disappeared entirely later, though the uterine catarrh was still present.

Case 3 was a woman, æt. 48, who complained of bleeding from the genitalia resultant from scratching. Suspecting malignant disease, the high amputation of the vaginal portion was made. The suspicion was not confirmed. The abnormal secretion and the hemorrhage continued after the operation; notwithstanding this, the itching increased to so high a grade that the patient became very melancholy, and sought to commit suicide. The location of the pruritus was a place on the perineum, where a defect was found covered with pale mucous membrane, dating from one of the births. After a perineoplastic operation, the pruritus disappeared and has not returned again. As especially noteworthy, the author mentions the fact that the perineal defect had remained many years without causing trouble. The pruritus, which at the time of the severe hemorrhage and the separation of material from the broken-down vaginal portion was only moderately great, after the removal of this broken-down tissue began so strong in the place on the perineum. The author cannot give an explanation for the peculiarity.

Case 4 was one in an old maid, in which the author had assisted Olshausen, in Halle. In this case the mucous membrane of the hymen, up to the labia minora, was removed with success.

Jejunostomy.

Mr. C. H. Golding-Bird thus reported to the Clinical Society of London:

The case upon which the reader founded his remarks was that of a man, æt. 46, who had had symptoms of pyloric obstruction for ten months. When admitted into Guy's Hospital a tumor could be felt at the seat of the pylorus, and the man's general condition was one of extreme emaciation through the inability to retain the food he took, and his voluntary abstaining from eating on account of the pain he suffered. After three weeks' treatment under Dr. Carrington, of drugs and washing the stomach out, he passed into Mr. Golding-Bird's hands; and when all the risks had been explained to the patient, and all methods of palliation had failed to improve his condition, arrangements were made to explore the diseased parts, and remove them if expedient. Mr. Golding-Bird, therefore, on October 25th, 1885, cut down on the pylorus with a view to performing pylorectomy, following the lines laid down by Billroth; but finding the tumor adherent to the liver, determined to go no further in the radical operation, but to convert it at once into a palliative one of opening the jejunum—in other words, of performing jejunostomy. Having seized the jejunum two inches from the duodenum, it was held up on a pair of tongue forceps, whilst the wound in the parietes was united; to the lower or right end of this wound was the jejunum now stitched by interrupted sutures. The patient suffered in no way as the result of the operation. He was fed partly by rectum, partly by mouth, until the third day, when the bowel was opened, and food administered solely through the fistula. It was observed that as long as the meal amounted to a pint, or nearly so, the patient each time he was fed had a severe attack of indigestion, but that this ceased when the meal did not exceed ten ounces. On this the author founded the suggestion that some cases of indigestion were due to the pylorus allowing too free passage of chyme, rather than to anything wrong with the gastric or pancreatic secretions. Everything went on perfectly well till the ninth day, the patient putting on flesh; but on that day, through an error in feeding him, some food passed into the peritoneum, and he died in twelve hours. The post-mortem showed such adhesion to, and infiltration of the liver, of the cancerous pylorus, that pylorectomy could not have been performed. Except the narrow track made by the probe, and along which the food passed into the peritoneum, the adhesions of bowel and parietes were perfect. The author then reviewed the operation of pylorectomy, speaking in favor of it in suitable cases, and the operation of gastro-duodenostomy, as performed by Wölfler, and pointed out the great drawback in this operation, that the stomach is not relieved of its physiological duties at all, the pylorus not being required to act. For the operation of jejunostomy, as he termed the one that he detailed, he claimed that, whilst it possessed the same disadvantage as gastrostomy, in that the patient had to be fed through the fistula, it was otherwise the best palliative operation for pyloric cancer, inviting less risk than gastro-enterostomy, and requiring less interference, in its performance, with the other viscera. By duodenal digestion, he also pointed out, full nourishment could be assured, and there was, for physical reasons, less chance of regurgitation of food than after gastrostomy; regurgitation in these cases being a serious drawback to that operation in œsophageal constriction.

Gastrostomy.

Mr. C. T. Dent reports this case in the *Med. Press*, December 2, 1885:

The patient, a man, æt. 44, had suffered for about four months from symptoms of malignant disease of the œsophagus. When admitted he could swallow fluids with difficulty, and had occasional attacks of vomiting. A bougie, passed a long way down, met with an obstruction, and struck against something hard. Gastrostomy was advised, but the patient did not consent to the operation till nearly two months later. The first stage of the operation was performed by means of a curved incision in the left linea semilunaris; the stomach was easily recognized, and the part lying beneath the wound was attached to the surface. This part was subsequently proved to be rather near the pyloric end. The stomach was opened on the fifth day. For the first few days subsequently the man improved, but then the stomach became very intolerant of food, and constant thirst was complained of. The patient died on the eighth day after the second operation. Post-mortem, extensive malignant ulceration was found, seven inches and a half below the thyroid cartilage. A large part of the wall of the œsophagus was destroyed, and the edges adhered to the spine. The right bronchus and lung were involved. Lower down still, a second malignant growth completely blocked the œsophagus. There was no trace of peritonitis. The author remarked that in this case the operation probably neither accelerated nor retarded death. Gastrostomy for malignant stricture was not,

in his opinion, justifiable as a "last resource," and could only be advocated in the hope of prolonging life. This it would do if performed very early. The occurrence of vomiting was a very valuable guide, perhaps the most important, as indicating the advisability of gastrostomy. The author cited another case where the œsophagus was affected at two distinct points, and pointed out that such instances were not infrequent, and formed an additional argument against œsophagostomy in cases of malignant stricture. Finally, it would be better to enlarge the abdominal wound if necessary, so as to attach a part of the stomach to the surface remote from the pylorus and near the large curvature.

A Case of Syphilitic Phthisis.

M. Gaudichier reports the following case (*Annales de Derm. et de Syph.*, No. 3, 1885). A man, aged 39, was admitted into the Hôpital St. Louis, under the care of M. Fournier, on March 1, 1884. The patient said he had been wasting for two months, and that he had lately become so easily fatigued that he was unable to work. He had only had a cough for a few days, and had not suffered from night sweats or hæmoptysis. After admission, however, he spat a blood-stained, muco-purulent fluid. At the left apex there were all the signs of a large and advanced cavity—cavernous breathing, gurgling, and cracked-pot sound on percussion. Over the right lung, the breathing was somewhat blowing in character, with subcrepitant râles. M. Fournier diagnosed tuberculosis of both lungs, but most advanced in the left. The left tibia was enlarged and irregular, and on the same leg were two gummy ulcers. There were also nodes on the right tibia and left clavicle. The discovery of these signs led to the administration of iodide of potassium in a daily dose of 60 grains. After two months' treatment, the signs of lung mischief had almost disappeared, and the nodes had considerably diminished in size. Eleven months later, the patient was again seen. His general health was then excellent, and the chest-lesions appeared to be completely cured. The patient, however, had only continued the iodide for a month after his discharge, and ulceration had reappeared on the left leg. Attention is directed to the fact that there were no physical chest-signs in this case, by which the diagnosis between tubercle and syphilis could be made. It was only by the effects of treatment that the true nature of the affection became evident.

Treatment of Catarrhal Phthisis, of Hæmoptysis, and of Chronic Bronchitis, by Terpene.

In the *Bulletin de l' Académie de Médicine*, No. 30, 1885, Prof. Germain Sée gives the following *résumé* of his paper on this subject:

1. It diminishes and quickly arrests purulent expectoration in catarrhal forms of phthisis. Whether the muco-purulent secretions proceed from the bronchi, irritated by tubercles, or from the walls of pulmonary cavities; whether the malady is at an early stage, or at a phase of purulent breaking down, or even of cavities already formed; terpene should be used whenever the formation of pus is sufficiently abundant to tire the patient, to exhaust the strength, or to cause him to waste away.

2. It should be used with success in the hæmoptysis of the early stages of tuberculosis; that is to say, when the disease has not yet developed large cavities, with aneurisms of the pulmonary arteries.

3. In the treatment of pulmonary catarrhs, of chronic bronchitis not dependent on asthma, and only producing dyspnœa by choking the bronchi, terpene constitutes the best method of lessening bronchial hypersecretion.

4. The action is quick, sure, and free from physiological inconveniences, rendering it preferable to preparations of syrups of turpentine or tar, or of shoots of pine, which contain so little of it; and to essence of turpentine, which is not tolerated. It even offers advantages over creosote, on account of its perfect innocuity and easy digestion.

5. The best way of administering this medicine is either in the form of pills or tincture, and the best dose is one gramme.

6. In catarrhal, or emphysematous, or nervous asthma, which is to be distinguished from primary catarrh, iodine and pyridine have an incontestable superiority.

The Influence of Antipyrin on Nitrogenous Metamorphosis and Assimilation in Febrile Patients.

In a preliminary note in the *Vratch*, No. 30, 1885, p. 489, Dr. P. A. Walter publishes the outcome of his observations (on several febrile patients at Professor V. A. Manasseïn's clinic) undertaken in order to answer the question—"Does or does not antipyrin fulfill the conditions which are essential for every useful antipyretic remedy?—that is, does it or does it not diminish the process of decomposition of tissues or the production of heat, without any interference with assimilation of

the food, and without any harmful action on the heart, brain, etc.?" The patients (with pleuro-pneumonia, bacillar phthisis, typhus fever, pleuritic exudation) experimented upon received for six days only milk, cranberry juice with water, and common water. For the first three days of the observation, no antipyrin was given; for the next three days the drug was given in such doses as to constantly keep the temperature at an apyretic level, the purpose being attained by daily doses varying from 3 to 8 grammes. The milk and urine were analyzed after Kjeldahl-Borodin's method. The results as given by Dr. Walter are these:

1. Antipyrin is an excellent and sure anti-febrile remedy, free from any unpleasant accessory action.

2. While lowering the febrile temperature, antipyrin also lowers the nitrogenous metamorphosis of tissues, without producing any injurious effects (such as enfeeblement of the cardiac action, action on the brain, etc.).

3. In the majority of cases, the assimilation of nitrogenous substances of the food undergoes improvement under the influence of antipyrin.

The author notes also that antipyrin sometimes exercises a favorable influence on diarrhœa.

Spasmodic Croup Complicating Measles.

Dr. A. B. Holder, of Paris, Miss., thus writes in the *St. Louis Courier of Med.* for December:

Louisa M., 19 years old, nervous temperament, had measles, progressing normally till second day of eruption, October 15, at night. At 7 or 8 p. m., she was observed to be voiceless, and breathing with difficulty. The breathing grew more difficult, and presently she failed in an inspiration. There was evidently a spasmodic closure of the air-passage. The spasm yielding gradually, there was noisy and then easy breathing, and presently other spasms, returning every few minutes for half an hour, and similar attacks of shorter duration succeeding this till 3 a. m., and recurring for two nights thereafter, never occurring in daytime.

The individual paroxysms lasted from a moment to twenty or twenty-five seconds. The trouble was solely in inspiration. In the interval breathing would be normal. She was conscious throughout the attacks. She had slight pain and dryness in the throat, partial aphonia for several days, the usual slight bronchitis and cough. Patient never, even as a child, had "croup" before. Temperature 100° to 101°, pulse 80 to 90, and unaffected by paroxysm. Patient now convalescent (October 22).

Meigs and Pepper, Tanner, Wood, etc., mention pseudo-membranous croup as a rare and fatal complication. Bristowe states that "very often croupy symptoms manifest themselves," but leaves us ignorant whether of membranous or spasmodic form.

Dr. Hardaway alone, of writers consulted, clearly mentions the complication.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A neat reprint of 120 pages, entitled "A Study of Air-Embolism," appears from the pen of Dr. N. Senn, of Milwaukee. It is an exhaustive monograph on the subject.

BOOK NOTICES.

Organic Materia Medica and Therapeutics. By James Y. Simpson, M. D. 8vo., pp. 337. J. H. Vail & Co., New York.

The labor of compilation and abbreviation in this work appears to have been carefully performed, but from the nature of the subject, many of the statements made, especially with regard to the action of drugs, are unsatisfactory and need support. With this proviso, the volume is a convenient one for pharmaceutical and medical students. The author makes no reference to the work of similar title and upon the same plan, which was written by Prof. L. E. Sayre, of this city, and published a few years ago at the office of this journal.

Essentials of Vaccination. By W. A. Hardaway, M. D. Cloth, 8vo., pp., 146. St. Louis. J. H. Chambers & Co., 1886.

There is room in the book market for just such a hand-book as this. Even among physicians there are a great many points about vaccination, especially about the production and use of bovine virus, of which they are ignorant. We know this from personal observation. From an examination of Dr. Hardaway's manual, we think he covers the more essential points, though his scheme is a little too large, or his book too small, to go into as many details as in our opinion would be beneficial to his readers. We hope he will soon be called upon to prepare a second edition, which can be amplified.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE MEDICAL RECORD AND THE CONGRESS.

The *Medical Record* takes exception to our recent editorial, and says:

"We are pained to see the MEDICAL AND SURGICAL REPORTER is departing from its usual conservative and straightforward methods in order to misrepresent the status and statements of the *Medical Record.* Quoting only a portion of our editorial of January 9, in which we published the letter of Dr. Johnson, of Paris, it makes us say that 'a considerable part of the best men of the profession have been excluded from the International Congress.' Our contemporary must know that this is not the whole of the sentence, and it misrepresents our meaning when thus quoted alone. We are forced to add further, that our esteemed contemporary appears to have forgotten that the management of the proposed Congress is not now in the hands of the American Medical Association, but in those of an Executive Committee which has declared itself entirely irresponsible of that body. Appeals to the 'loyalty' toward the Association, therefore, are simply a process of beating the wind. Finally, our ever-welcome contemporary should remember that italics and small caps cannot make an inherently weak argument vigorous. The REPORTER is unjust in attributing to us motives of action which do not exist. It is unfair, we think, to its readers, in giving them a distorted history of the present status of medical feeling as regards the Congress."

To commence with, the MEDICAL AND SURGICAL REPORTER, far from departing from "*its usual methods,*" is now pursuing the course that it adopted and that made it a success long before the *Medical Record* saw the light of day. The REPORTER was founded as a journal for the profession, *as a body,* and never has, does not now, and never will, acknowledge subserviency to any clique, set, or coterie of medical men. So long as the American Medical Association represents the *mass* of the profession, so long will it receive the hearty support of the REPORTER.

Secondly, our quotation does not misrepresent the meaning of the *Record,* for in addition to quoting "a considerable part of the best men of the profession have been excluded from the International Congress," we were careful also to quote "or have been forced in self-respect to withdraw from all connection with it," a clause that the *Record* would have done well to leave out, as it can only be construed that the *patrician* could not affiliate with the *plebeian* without fear of contamination—that the New

York and Philadelphia leaders were "forced in self-respect to withdraw themselves" from all connection with the vulgar herd, the mass of the profession. This does not sound like consistent language from a journal that calls itself a journal for the whole profession, but it does exactly fit, "shust like de paper on de wall," to an organ that is, as we claim the *Medical Record* is, the champion of the autocrats.

Thirdly, we do not forget anything; we have heard a rumor to the effect that the present Executive Committee has declared itself independent of the American Medical Association; we doubt it, but if true, we have also heard of the Emperor who battled with and claimed to have conquered the sea. Let the Committee *declare* all they please, no one with a grain of sense (and we always supposed the editor of the *Record* abundantly provided with such commodity) would give a fig for such claims. They *are not* independent of the Association, and they know it; they are in accord with the Association, and the editor of the *Record* knows that. If they were to attempt any autocratic methods with their creator, the Association who made would unmake them very quickly, and this journal would be gladly in attendance at the obsequies. Such a flimsy charge is unworthy of the *Record*, and if it has no better ammunition, we advise the editor to take off his war paint and "eat crow;" he is yet vigorous enough to digest it, but if he continues much longer in his present suicidal course, his assimilative functions will be so weakened that it will be then likely to produce a fatal case of "Collapsus Subscriptionum."

Fourthly, "appeals to the loyalty towards the Association" are not a process of beating the wind (the applicability of which we cannot comprehend), but steadfast loyalty to the profession is a means of beating the *Record*, that has been loyal only to the select few, foolishly dreaming that the mass of the profession have no minds of their own—that they would, calf-like, accept the dictatorial mandates of the autocrats issued to them through the advisorial columns of the *Record*.

If our younger brother had asked our advice before embarking on this unpatriotic and unprincipled warfare, we should have told him that, after years of experience, we were fully prepared to say that the mass of the profession are not sheep, to blindly follow a leader even to the slaughter-house; that they are wont to think and act for themselves—a fact that the *Record* seems now to have found out.

Finally, we would say that since our editorial friend does not hail from Boston, we would take issue with him, and contend that italics and small caps do serve to impress more firmly a fact, because they rivet attention to such fact; and since the caps were not at all used in argument (weak or strong) we will use them again to emphasize what we said before, and what is the reason for the course we have taken, "THAT EVERY TRUE PHYSICIAN UNQUESTIONABLY OWES HIS ALLEGIANCE TO THE AMERICAN MEDICAL ASSOCIATION."

Come on, Brother Shrady; we are determined to champion the American Medical Association, and the more you misconstrue our utterances, the better opportunity you afford us to expose your rebellious and unpatriotic position. We have unquestioned right on our side, and can always feel secure in our assertions.

By the way, you have forgotten to answer the two questions we asked you some time since: "Who started the ethical revolt in New York?" "What journal supported the rebels?"

DISAGREEABLE EFFECTS OF COCAINE.

The foreign medical journals still continue to publish reports concerning the effect of cocaine in all possible internal and external disorders. Though here and there—especially from ophthalmologists—complaints have been heard about certain effects of the remedy, which had not been expected, the general opinion amongst physicians still seems to be that the hypodermic injection of a small dose of muriate of cocaine does not only cause no annoyance to the patient, but is also innocuous.

Dr. Litten, in a debate about the action of this drug at the meeting of the Berlin Medical Society, held November 4, 1885 (*Deutsche Med. Zeit.*, November 12, 1885), cautions against the too general use of cocaine. He says that in some individuals it exerts a powerful influence upon the circulation, it increases the blood-pressure, excites the heart, and acts as a diuretic, as the urinary secretion is augmented in quantity under its use. In consequence of this action, the patients feel an increased warmth, and some complain of a very annoying pricking sensation. Several of L.'s patients remarked after the injection that it seemed to them as if molten lead were running in their blood-vessels. In some very excitable individuals attacks of mania, occasionally very violent, have been known to occur immediately after such an

injection. This effect always ceases within from one to two hours, but may prove dangerous to some. Then others complain of a peculiar dryness in the throat, forcing the patients continually to make attempts at swallowing; and in some this symptom finally assumes the form of a severe pharyngeal spasm. This action of cocaine, which is rarely wanting, and differs only as to degree in persons, induced L. to try the effect of it in cases of profuse salivation, and in every instance the increased flow of saliva at once ceased after a hypodermic injection of cocaine. Again, others, instead of observing an increase of appetite, which has been said always to accompany the use of the drug, utterly lose it, and when the injection has been made in the forenoon, the patients are utterly unable to eat anything during the remainder of the day.

The various disagreeable effects mentioned in some individuals reach such a high degree, that actual danger to life seems to threaten the patient. Litten recommends, therefore, strongly, in all cases where it is possible, to prefer simple local application to the hypodermic medication. Dr. Böcker has used during the last two months the following methods to dull the sensitiveness of the soft palate in laryngoscopical examinations, and to induce anæsthesia of the Schneiderian mucous membrane for the painless removal of polypi. He takes a solution of muriate of cocaine of 20 per cent.; of this he drops a few drops on the mirror, and also dips the sound into it. A similar procedure is employed by him for the nose. In every case the local anæsthesia developed was sufficient and lasted long enough to enable him to perform the operation without causing the patient any pain or other disagreeable symptom. Only in two cases did he observe dryness and attempts at swallowing, with a choking sensation, as effects of the local use of the drug, but they were much milder than usually occurs after a hypodermic injection of the remedy.

Wherever it is possible, it may be well first to try the local application ere we have recourse to the subcutaneous method; and should the latter be employed, the dose of the cocaine should be as small as possible, at least until the fact has been determined whether the patient has a special idiosyncrasy against the drug or not.

CLINICAL TEACHERS.

We have already on two occasions adverted to the negligence and neglect of duty on the part of clinical teachers, in coming late, or, as frequently happens, entirely neglecting to come at all, to their posts of duty.

We dislike to make this exposé, for we dislike to let it be known that our clinical teachers, many of whom have world-wide reputations, have so little sense of the duty imposed upon them, and, impliedly, willingly assumed by them, when they accept their positions.

On a recent occasion we visited the Philadelphia Hospital, when Dr. Parvin delivered the very interesting lecture (he is a teacher who is always on time—let our readers make a note of this, for they can always count on his presence and on hearing something valuable and interesting) which we publish on another page. When his hour concluded (at ten o'clock), there was no one to succeed him (owing to some misunderstanding as to whose duty it was to lecture), and Dr. Parvin good-naturedly instructed the class for half an hour longer, when they were left, through somebody's fault, for thirty minutes to do and learn nothing.

The announced schedule of the Philadelphia Hospital provides for three hours of clinical instruction on each Wednesday and Saturday morning, yet we say from personal observation that it is a rare occurrence for this programme to be carried out.

Very many of our teachers in other institutions are derelict, but as the omission of duty is particularly marked in the Philadelphia Hospital, we call attention to it especially.

We have prepared a list of those who are punctual and those who remiss, and if any physician sending his student to the city desires to instruct him whose clinics to attend and whose to avoid, we will furnish him a list on application.

We are jealous of Philadelphia's good name, and realizing that it has the best clinical facilities in the United States, surpassed, in this respect, by no city in the world, we regret to see this good name being ruined by those to whom the utilization of these clinical facilities are entrusted.

Notes and Comments.

A New Remedy in Diphtheria.

Prof. Rossbach reported some time ago good results he had obtained from the employment of papayotin in diphtheria and croup. Several authors later contended that the remedy did not cure all cases. Rossbach,

who is known as a reliable and painstaking observer, has now published a reply to these attacks. (*Deutsche Arch. f. klin. Mediz.*, 1885, No. xv.)

Based upon many positive evidences, he maintains that while papayotin is no specific for these diseases, and can especially not cure cases that have lasted too long, and where the heart is already beginning to be paralyzed, it is by far the best remedy thus far known for the dissolving of diphtheritic and other false membranes. He says that if employed in time, it will make tracheotomy superfluous and greatly lessen the mortality, as the membranes can be destroyed as rapidly as formed, and thus further infection (as proceeding from false membranes) of the system becomes impossible, and the fever is averted. The only objection which Rossbach had against the general employment of this valuable drug is the fact that in grave cases, where the false membrane is very large, considerable quantities of the drug are needed, while the price is so very high.

Rossbach recommends papayotin so strongly, and his reputation for veracity is so well established, that the remedy should surely be tried on a more extensive scale. Our therapeutics for diphtheria have thus far been but very little satisfactory, and no drug should be neglected that promises any success. There seem to be no dangerous effects of the remedy, which is employed locally and in quantities sufficiently large to insure complete removal of the false membranes. These first become soft, and finally nearly fluid, and on examination of the detritus no cocci of any kind are found in the mass.

Influence of Chloral on Digestion.

From an article in the *Archives Ital. de Biologie*, vi. 3, p. 412, we learn that Professors Fiumi and Favrat had the opportunity, in a man suffering from a gastric fistula and insomnia, to study the effect of chloral on digestion. Finely cut up albumen was sewed up in tiny bags, and from twenty to forty grains of chloral were administered daily in divided doses, one an hour before digestion began, another during the meal, and a third two hours later. All scientific precautions to insure a correct result were employed.

The observations extended over a period of nineteen days. Hydrate of chloral, administered in from twenty to forty grain doses before or at the beginning of a meal, retarded digestion by increasing the secretion of mucus from the stomach, and thus thickening the gastric juice. This effect increases with the height of the dose, and it is specially strong if the remedy be taken while fasting. The acidity of the juice also diminishes, but before an hour is over it has returned to its normal. The secretion of pepsin is not interfered with, either as regards quantity or quality, so that the disturbance can be ascribed only to two factors: increase of mucus by irritation, and diminution of acidity. If the remedy be administered two hours after a meal, provided the dose is not more than forty grains, no effect whatever is observed concerning any influence of the drug on gastric digestion.

The authors, besides, demonstrate the fact that chloral is absorbed but slowly by the gastric mucous membrane, for one and even two hours after its introduction most of the dose was still contained unaltered in the stomach. This explains partly the fact, that its administration by the rectum is followed by a quicker and prompter effect than when given by the stomach.

Treatment of Colles' Fracture by a New Method.

Before the Rhode Island Medical Society, Dr. George F. Keene read a paper descriptive of this method, which consists in putting up the fracture with the hand extended nearly to a right angle with the arm, and supported by a wire splint. If the forearm is placed on a flat splint so that the fingers are flexed over the end, it will be noticed that the radius does not touch the splint at all, and the ulna only on its upper third. If, however, the hand is lifted until fully extended, the radius will touch the splint at its lower end, the thenar and hypothenar eminences of the hand being lifted out of the way. The flexors act at their best advantage when the hand is thus extended, and regain flexibility and strength rapidly when the splint is removed. When the hand is clenched, it moves quite perceptibly to the ulna side of the arm. In the treatment of this fracture, the flexor muscles should be placed at their best advantage, the extensor muscles should be placed at their greatest disadvantage, and the end of the radius should be brought down upon the splint.

To accomplish these ends it is only necessary to bend a piece of ordinary telegraph wire, first into the shape of an ordinary hairpin, then bend up sharply about two and a half inches of the closed end, flattening somewhat the top of the bend so that the fingers may rest easily upon it at their ar-

ticulation with the hand. The ends of the wire are fastened with a strip of tin curved to fit the arm, and with a second strip under the end of the radius.

Dr. Keene reported three cases in which his splint fulfilled all the conditions of success, avoiding pain and swelling during treatment, and preventing subsequent deformity and impaired function of the hand and forearm.

The Prevention of Mammary Abscess.

Dr. Philip Miall thus writes in the *Brit. Med. Jour.*, November 21 :

A method of treating inflamed breast after delivery may be worth notice in connection with Dr. Edis's paper on the use of support by a bandage or towel. Dr. Edis appears to use his method after every delivery, and, by beginning it before lactation is established, assures success; but one occasionally sees cases where abscess is on the point of forming, either from neglect or injudicious treatment, and where, consequently, something more is required.

I have repeatedly seen a hot, heavy, inflamed breast, with redness of skin, throbbing, and deep-seated pain, the pulse being 120 in the minute, yet these symptoms have disappeared in the course of a few hours under fomentation with hot water and ammonia. An ounce of carbonate of ammonia is dissolved in a pint of boiling water, and, when solution is effected, the temperature will scarcely be too high for fomentation with cloths dipped in the liquid. These must be assiduously applied for half an hour at least, and repeated two or three hours later if necessary. It is well to protect the nipples, though I have never known them to be injured. Relief is immediate, and more than three applications are seldom required.

Unless applied too late, or improperly, or some foolish rubbing or drawing with the breast-pump be used, contrary to orders, this remedy may be thoroughly relied on. I am indebted for it to Mr. Douglas, of Banbury, and as it has had a trial of thirty years in my hands, I can speak of it with some confidence.

A Reliable Remedy for Ozæna.

Besides the removal of the diseased bone, the only remedy which has thus far been considered to possess any value in ozæna has been chloride of zinc, and every physician will admit that its effect never answers the expectation.

A new preparation of aluminium, the aluminium acetico-tartaricum, has been discovered to be almost a specific in ozæna. Altenstart and Schaefer (*Deutsche Med. Woch.*, 23, 85,) have tried it in a large number of cases, and say that its effect is really surprising. The fœtor of the secretion rapidly disappears, the scabs become thinner under its use and drop off much easier, the atrophic mucous membrane assumes a healthy look, and within two weeks a complete cure may be established in all cases where the bone has not already been so diseased as to be loose like a sequestrum. Of a fifty per cent. solution, one teaspoonful is usually added to one-half to one pint of water. It possesses about the same caustic properties as a solution of nitrate of silver of one to five, and is also indicated in the same morbid conditions of the mucous membrane as the latter drug, but it seems to have a specific effect upon the mucous membrane of the nose and of the larynx. In ulcerations, for instance, of the larynx, its effect is far more rapid than that of boric acid.

We do not know whether the remedy has reached this country, but it will be rapidly imported whenever some of our leading physicians conclude to make a trial of it.

A Painless Escharotic.

The *Med. News* tells us that Mr. C. E. Jennings has recorded in the *Lancet* for October, 1885, two cases in which he used cocaine to alleviate pain, whilst caustics were applied to cancerous growths. One patient was aged 73, and suffered from extensive scirrhous ulceration of the right breast. The surface of the ulcer was covered with rugged, irregular granulations, which bled upon pressure; the veins around the growth were much engorged, and the pain was increasing. After painting the ulcerated surface with a ten per cent. solution of hydrochlorate of cocaine, a paste was applied consisting of cocaine, potassa fusa, and vaseline. After some minutes a burning sensation was experienced; then the paste was quickly removed with the charred tissue, by means of pledgets of cotton-wool previously moistened with water. The denuded surface was again painted with cocaine solution, and the compound paste reapplied. By this means, more than a tablespoonful of cancerous growth was removed by a rapid and painless process. The next day a clean, smooth, and bloodless surface, insensitive to the touch, was presented. By this means most of the scirrhous mass was removed after a few applications. In the second case, the author

destroyed a cancerous growth of the os and cervix uteri, by means of sticks of potassa fusa, and a ten per cent. solution of cocaine

---

Massage of the Thoracic Organs.

The *Med. Record* says mechanical therapeutics has acquired for itself in recent years a settled place in medicine, and its advocates are constantly endeavoring to enlarge its scope and widen the field of its usefulness. In the *Allgemeine Medicinische Central-Zeitung*, No. 20, 1885, Dr. Emil Schlegel reports some cases of pleuritic effusion, in which absorption of the fluid would appear to have been induced or accelerated by repeated blows upon the chest-walls. The closed fist was used, the blows being struck by a motion of ulnar flexion at the wrist-joint, combined with supination of the hand. The ball of the little finger came in contact sharply with the ribs and rebounded, the hand turning back into radial flexion and pronation. About two blows were made in a second, or six hundred in the space of five minutes. Two sittings were had each day. Under this mode of treatment a successful result was obtained, in some cases in a much shorter period than usual. The author has tried "concussion strokes" (*Erschütterungsschläge*) only in the case of pleuritic effusions, but he believes that it might be equally useful in promoting absorptions in other portions of the body, as the intra-cranial cavity, spinal canal, etc., which are inaccessible to the ordinary manipulations of massage.

Hemorrhage from a Wound of the Cervix Uteri Simulating an Impending Abortion.

To the Chatham Med. and Surg. Society, Dr. McKeough related the case of a woman who had had two previous miscarriages, and who he supposed was threatened with another. The patient was between three and four months pregnant, complained of some pain in the pelvis, which, however, was not intermittent, and judging from the condition of her clothes and bed, there had been considerable loss of blood. Pulse was quick and feeble; her countenance pale and anxious. Numerous clots were removed from the vagina, which was tamponed with pledgets of cotton-wool, soaked in boro-glyceride. The following day the patient admitted that she had attempted to produce an abortion by violence, a large knitting-needle and a catheter being the instruments used. After the tampon was removed an examination of the cervix was made, and revealed an old bilateral ulceration. In the posterior everted lip was a recent, deep, ragged wound, to which a clot was attached. Its removal caused a fresh spurt of blood, which was controlled by pressure. This occurred six weeks ago, and there have been no symptoms since of a premature expulsion of the fœtus.

Double Popliteal Aneurism.

Before the New York County Medical Association, Dr. I. B. Read read the report of a case in which the aneurism in one leg developed after the other had been successfully treated by ligation of the femoral artery, after various other expedients had been fruitlessly tried. Ligation of the femoral was performed in this instance also, and both tumors have entirely disappeared. From his experience he would lay down the rule, never to be departed from, that, when compression can be made in the artery above the diseased portion, it should always be resorted to as a means of lessening the danger consequent upon ligation of the artery. In popliteal aneurism, if compression of the femoral is made, the blood, being shut off from the latter, gradually distends the profunda and other smaller branches, and if, in the meantime, the surgeon can induce the formation of a clot within the aneurismal sac, so much the better. But in case it is necessary to ligate the femoral, heat and nourishment, and sensation will thus be successfully maintained in the lower part of the limb, and the danger of gangrene avoided.

Schultz's Method of Resuscitating the New-Born Child.

At the last annual meeting of the Medical and Chirurgical Faculty of Maryland, Dr. Neale (*Med. Record*), illustrated Schultz's method of resuscitating the new-born child in case of asphyxia. The child is held by the shoulders, the thumbs resting upon the thorax, the child's head toward the operator, and its anterior surface to the front; it is then swung upwards so that its feet perform a revolution, and lie between the head and the operator's body, the trunk being then in a state of forced flexion. The original position is then resumed by a reverse movement, and the repetition of these movements constitutes the method. Dr. Neale regarded it as more effective than Marshall Hall's or Sylvester's, and related a case in which resuscitation had been secured after ten min-

utes, the measures mentioned and all others having been tried in vain.

Congenital Absence of a Lung.

Dr. Wenzel Gruber has recently published, in Virchow's *Archiv*, notes of two cases of congenital absence of a lung. The first was described by him in the *Oesterr. Zeitschrift für praktische Heilkunde*, in 1870. The right lung was absent in a female stillborn child. On December 10, 1884, he found the left lung absent in a female child born prematurely. The child had also an accessory liver, and three accessory spleens. The left thoracic cavity was occupied above by the left lobe of a very large three-lobed thymus, enveloped in a distinct fold of the pleura given off from that membrane as it passed over the left mediastinum. Inferiorly, the heart and mediastinum filled the left side of the thorax. The right lung was large, and not divided into lobes. An accessory liver lay in the ligamentum triangulare sinistrum, six millimètres apart from the main part of the liver. It was oval and flattened, and a centimètre and a half in its longest diameter. The three accessory spleens were, as usual, in the gastro-splenic omentum.

A New Heart-Tonic.

Prof. Wagner recently employed the new heart-tonic, the nitro-salicylate of caffeine, in his clinic in Buda-Pesth, on twelve patients (*Oroosi Hetilap.*, No. 32, 1885). The daily dose varied from 3 to 18 grains. The results were the same as those observed by Riegel. The remedy is a rival of digitalis, but has the great advantage of being more rapid, and never accumulative in its effect. The only drawback seems to be, that with the discontinuance of the remedy its effect also quickly ceases. At the beginning but small doses should be administered, as many patients evince a peculiar idiosyncrasy against the drug.

The remedy is indicated in all cases where compensation has ceased. It here causes a regular and stronger action of the heart, and decided increase of the urinary secretion. All the disagreeable after-effects of digitalis are absent in the employment of nitro-salicylate of caffeine.

Disinfection of Apartments by Volatilized Corrosive Sublimate.

The *Med. News* says that Delbastaille, in *The Annales de la Société Mèdico-chirurgicale de Liège*, highly recommends the method of disinfection employed by Koning, of Göttingen. This procedure consists simply in closing the doors and windows of the apartment, and then throwing about two ounces of bichloride of mercury upon a pan of live coals. The room is to be quitted immediately, and should remain filled with the vapors of the sublimate for three or four hours. It is then aired for several hours, the ordinary precaution being taken to prevent the entrance of the corrosive vapor into the respiratory passages. In order to prevent injury from such portion of the sublimate as may still cling to the room, the subsequent volatilization of sulphur in the apartment, in the ordinary manner, is desirable.

Hemicrania.

In many cases of hemicrania the pathogenic cause is unknown. That the sympathetic ganglia have something to do with it, has long ago been proven by Eulenburg and others. Dr. C. Weigert (*Virchow's Arch.*, 176, '85,) has recently discovered an invariable disturbance in the formation of the supra-renal capsules in cases of hemicrania. Generally they were too small, and in one case, which may be of importance, they were totally wanting. In the same case, the superior cervical ganglion of the sympathetic was also absent. It is possible that the hemicrania as well as the morbid condition of the supra-renal capsules are both symptoms of an affection of the vesical ganglia. This would also explain the favorable result which is often obtained in cases of hemicrania from galvanization of the cervical ganglia.

Optic Neuritis in Children.

The object of a note by Dr. Saundby, in a recent number of the *Birmingham Medical Review*, on the presence of optic neuritis in children, is to draw attention to the possibility of the occurrence of double optic neuritis not depending on coarse intracranial disease or morbus Brightii. Two cases of optic neuritis are recorded, in both of which the patient was hypermetropic, and in neither was there any certain reason to suspect cerebral mischief or Bright's disease as the cause. Reference is made to the suggestion of Dr. Gowers that hypermetropic eyes are specially liable to suffer from optic neuritis. Unquestionably the subject is one of considerable interest, and not solely to neural pathologists. Dr. Gowers has pointed out the occurrence of optic neuritis in at least two

diseases, which are not unfrequently regarded as of functional order—chorea and anæmia.

The Sacrum as an Index of Race.

Professor Turner has communicated to the Edinburgh Royal Society a note upon the human sacrum considered as an index of differences which obtain between the skeletons of various races of men. He has found, as the result of a series of measurements, that this bone is not uniform in the relations of length to breadth in the various races of mankind, but that in some races it is longer than it is broad, whilst in others the reverse of this holds true. Some interesting data with regard to the "sacral index" in a variety of races were contained in the paper.

Oil of Sassafras for Neuralgia.

This remedy is highly lauded by Dr. Thomas J. Miller in the *Virginia Medical Monthly*, who says that it may be given with more safety than the veratrum viride, and in the same diseases. In despondent, hysterical women, he has no doubt it would have a charming effect; and in fevers, and other cases of sanguineous engorgement, or of cerebral tendencies. He suggests that it might be a most eligible mode, whenever convenient, of giving it in a glass of soda water.

Uncontrollable Vomiting of Pregnancy.

In the *Boston M. and S. Jour.*, December 24, Dr. O. W. Doe reports a case wherein no remedy seemed to do any good, and the woman was frightfully emaciated. The uterus was anteverted, pressing down into the pelvis. Tampons were inserted morning and night. Finally, one morning, after removing the tampon and pushing the uterus as far up as possible, and backwards, the nausea left, never to return.

Chronic Ulcers.

Dr. W. P. Howe, of Charleston, Mo., writes to the *Journal American Medical Association*, "that *lime* procured from barrels that have stood open for some time, sprinkled upon chronic ulcers, will cure them when everything else, usually prescribed, fails. . . Cleanse the ulcer with warm water and soap once every two days and fill the sore with lime; no more bad odor, no more pain, and a remedy so cheap that it is within the reach of every one."

Correspondence.

Hydrophobia and Pasteur's Remedies.

Eds. Med. and Surg. Reporter:

Heretofore no cure has been discovered for this frightful disease, and the only hope for favorable results is placed in the discovery of preventives. The mad-stones, elecampane, skull-cap, and all the other once celebrated prophylactics, have proved disappointing, and are being discarded. Should M. Pasteur's new system of inoculation prove successful, it will be a great boon, not only to the medical profession, but to mankind. Until, however, M. Pasteur shall have succeeded in curing a case of fully-developed canine rabies, the verity of his system remains in doubt, and to my view the outlook is not promising. The analogy between hydrophobia and small-pox is slight, if there is any. In the latter, inoculation mitigates the violence of the disease; it does not cure it. The greater mildness of inoculated over natural small-pox may, I believe, be easily explained. Natural contagion is carried by the atmosphere, and being inhaled by the patient, sets up a poisoning ferment in the blood; in from eight to sixteen days—called the period of incubation—fever sets in, the poison in the blood is carried to the capillary vessels of the skin, and the disease appears in the form of a specific eruption. The skin, therefore, is the final seat of the disease; the initial fever is the effect of the blood-poisoning. By inoculation, this process in somewhat reversed. By developing the disease in the first place on the skin, you escape the general contamination of the blood during the incubative stage; the initial fever is avoided and the disease is rendered milder and more safe through the total abolition of the first stage; the true contagion of the disease being unchanged. One thing remains to be investigated—will inoculation mitigate the severity of the disease if practiced after the contagion has been taken into the system? Vaccination, as I know from experience, will not; neither, as I believe, will inoculation; and, not until M. Pasteur can show that his patients have been actually infected—a difficult conundrum, by the way, —can any reasonable faith be placed in the reliability or success of his experiments. There is this difference between small-pox and hydrophobia, that in the former the contagion is conveyed through the atmosphere, the latter is only communicable by wounding—inoculation, in fact; and it is not possible that the insertion of the poison by

means of a lancet will counteract the effects of the same poison inserted by means of a dog's tooth. In natural small-pox the contagion is carried by the arteries to their extremities in the skin, where it is finally developed—as was before explained; in hydrophobia the contagion is believed to attack a peripheral nerve, whence it slowly progresses to some of the great nervous centres, the large ganglia, and possibly the spinal cord, when, having arrived there, the fatal convulsive symptoms follow; and it would seem that, to be efficacious, inoculation should be made in the final centre, if that can be distinctly located. Any puncture of the spinal marrow, with or without the addition of a specific poison, would be dangerous if not fatal, therefore unjustifiable; and to reach the cervical ganglia or solar plexus would be out of the question. Any operation on the skin would be manifestly futile. What seems to me an insurmountable objection to M. Pasteur's plan is, that hydrophobia differs from small-pox in being invariably fatal, and a *milder degree of fatality* to be caused by inoculation is all that can be expected—*cui bono?*

I do not call M. Pasteur a crank or impostor; I simply believe he is mistaken—his fancied success resting on the fact that a very small proportion of persons bitten by mad dogs ever go mad.

The most reliable prophylactic for hydrophobia is to excise the bitten part as soon as possible after the injury. Should the wound be small, or if so lacerated or in such position that this cannot be easily or safely done, then, after careful ablution, to apply caustic in such manner as to reach all the injured parts; and for this purpose I believe the best would be *arsenic*, in the form of Fowler's solution applied on lint, to remain for about twelve hours; then poultice until the slough separates. Nitrate of silver is not to be relied on. There is no danger and small expense in this mode of treatment—a great saving in the latter regard compared with a trip to Paris or St. Louis.

JOHN T. HUDDLESON, M. D.

Lancaster, Jan. 1, 1886.

Ligating the Umbilical Cord.

EDS. MED. AND SURG. REPORTER:

In your number of October 17, 1885, I notice an article upon "An Original Method of Ligating the Umbilical Cord."

In the early years of the war, when I was serving with my regiment along the Atlantic coast of the Southern States, and upon the Sea Islands, I employed leisure hours in talking to the slaves and their bright-eyed pickaninnies. In every instance, when I asked a mother the age of her baby, and I had hundreds of occasions to do so, the invariable reply was: "Why, bress de Lord, Massa, de nabel string been tied dis six weeks," or whatever number of weeks the child had been born, in cabin or cotton row, depending much upon the accidental whereabouts of the mother at that event.

The reckoning of the child's age was kept in that way—from the tying of a knot in the umbilical cord as close up to the body as possible. The effect of this was visible upon every naked youngster, and quite noticeable in after life; the navel, instead of being depressed, protruded. This is certainly a primitive method of preventing hemorrhage, but I never knew a child to have hemorrhage after this operation. Not being a physician, my knowledge is limited; still, I record what I know.

By the way, while speaking of umbilical cords, have any of your numerous readers, in looking at any picture they ever saw of Adam and Eve, noticed that delightful "bull which is not Irish," that they are always represented as having once had umbilical cords? CHARLES MCILVAINE.

Philadelphia.

NEWS AND MISCELLANY.

Huxley on Science and Medical Teaching.

At a meeting of the Royal Society, Prof. Huxley, in an address of remarkable ability and power, took leave of the great society whose presidency he has filled with so much honor, received from and reflected on that high office. He reviewed the progress of biological science, and dwelt especially on the vast accessions to human knowledge derived from the study of parasitism and bacteriology. This he classes as among the most luminous of the recent achievements of science, and one destined to have an increasing effect in throwing light upon the dark places of medical and biological science. He referred to the recent researches during the year of Dr. Klein, Dr. Roy, and his colleagues, into the specific origin of cholera, carried out in India and in Spain. Touching upon a subject of especial medical interest, he said:

"As a member of the Senate of the University, I am necessarily greatly interested in such projects, and I greatly regret that I

have been unable to take part in the recent action concerning them. This is not the time or the place for the discussion of any of these proposals, but many of my hearers must be as warmly interested in them as I am myself, and it may not be out of place to submit two questions for their serious consideration. In the interests of science, will any change be satisfactory which does not lighten the linguistic burden at present imposed on students of science and of medicine by the matriculation examination? And, again, in the interests of science, will any change be satisfactory which does not convert the examining university into a teaching university? And, by this last term, I do not mean a mere co-operative society of teacher-examiners, but a corporation which shall embrace a professorate charged with the exposition and the advancement of the higher forms of knowledge in all its branches. The future both of pure science and of medicine in this country is, I think, greatly interested in the answer which Fellows of this Society, after due meditation, may be disposed to give to these questions."

A Remarkable Instance of Longevity.

The *Popular Science News* for December publishes a portrait of Madame Girard, a native of the town of Saint-Just-de-Claix, in France. According to the parish records, she was born on the 16th of March, 1761, and is therefore a hundred and twenty-four years old. Like the traditional old lady of all countries, she can sew without using spectacles, and her hearing-powers are still good. Her memory, however, is very much impaired; and she remembers little of the events of her long life. She is still active, and carries her own wood and water, besides doing all the work of her modest house.

Her diet is quite simple, and consists principally of vegetables, with little or no meat. After every meal she indulges in a glass of wine or brandy. The *News* goes on to say: "Our contemporary, *La Nature*, to which we are indebted for the portrait, gives a list of persons, in France and elsewhere, who have exceeded the age of a hundred years. It is surprisingly large, and includes the well-known Thomas Parr, who died at the age of a hundred and fifty-two years, and a Frenchman named Priou, who died in 1838, in his hundred and fifty-eighth year.

It should be remembered that in England and Europe the records of births are much more carefully kept than in this country, and these remarkable ages appear to be well authenticated. Census returns show that in France, during the years 1824 to 1837, there were between a hundred and eleven and a hundred and seventy-five centenarians; while in Russia, in 1838, there was the surprising number of twelve hundred and thirty-eight. They also show that the average length of life is constantly increasing, and the time may yet come when persons a hundred years old will excite no more curiosity than one of eighty years at the present time."

The Doctor's Peculiar Danger.

The *Medical Age* deals with a delicate subject in the following skillful manner: "The physician, especially if he has been favored by nature with physical attractions, is above all men subject to sexual temptations. His relations to his female *clientèle* are of that secret and confidential nature which tends to familiarity. Weak women, who are diffident and shy to all other males, frequently conceive for their physician a passion which it would require but a slight response to convert into a crime. We apprehend there are few of our readers whom professional experience has not convinced of this frailty (which may, after all, be more or less physiological) on the part of the weaker vessel. In view of this fact, it is very complimentary to the profession that there are so few scandals chargeable to it. As compared with even the clergy (the especial conservators of morals), physicians stand well in this respect. Doubtless, too, not a few of the scandals chargeable to medical men have no sufficient foundation, the peculiar relations of the doctor to his female patients laying him especially open to the schemes of the blackmailer."

The Ladies' Tipple.

The *Med. Record* says: That popular abomination known as "Beef, Iron, and Wine," which is now sold so extensively, not only by druggists, but by tradesmen of various kinds, deserves a little special attention from the medical profession. It is an agreeable mixture to the sight and taste; its name is a triple combination of seductive mononyms; while taken into the stomach, it acts as a gentle "pick-up" to the worn and oversensitive nerves of the ladies. It has in consequence become a popular if not a fashionable tipple, and is indiscriminately used to an extent that is, we believe, not entirely free from danger. Every medical man knows that the amount of actual beef or food in these various preparations is insignificant, and that it is the wine, after all,

that makes them liked, and that leads so many persons to purchase their second bottle.

There is no good reason why this mixture is allowed to be sold by those unlicensed to sell wines, and if the law supports the practice, it is the duty of physicians at least to try and lessen it. Inebriety can result from these tipples.

Rapidity of Flight of Carrier Pigeons.

The *Revue Scientifique* says: The distance of Paris from Versailles is 20 kilometres, and the Paris pigeons in 1873 conveyed the minutes of the Académie des Sciences in 10 minutes, which is at the rate of 2,000 metres per minute. The same rapidity has been attained between London and Dover; the distance being 113 kilometres, as the bird flies, from Paris to Moulins (290 kilos), a rapidity of from 1,600 to 1,700 metres has been attained. These figures, however, are maxima; and for distances up to 500 kilos in clear weather the mean flight scarcely exceeds 1,000 metres, while in stormy weather it only reaches 600 or 700 metres.

Abnormal Mobility of the Tongue, with Ability to Project it into the Naso-Pharynx.

Dr. Phelps, of Corry, Pa., writes to the *Med. Record* that a man who lives about a mile from that city, who is about forty-five years of age, came to him about a year ago for the removal of a polypus from the nose. He saw him several times pass his tongue into the naso-pharynx with perfect ease. The tongue is slightly pointed, and the frænum linguæ is apparently absent for some some distance under the tongue. There is nothing abnormal in the formation of his mouth. He says he has possessed this ability for twenty years.

Porro's Operation in Japan.

In the *Berliner Klinische Wochenschrift*, October 19, is published a successful case of Porro's operation by two Japanese, Drs. Omori and Jkeda, of Fuknoka, being the first instance of this operation being performed in that country, where, however, ovariotomy has been performed. The infrequency of Cæsarian section in Japan is explained by the rarity of true rickets, and especially of osteomalakia, in that country. The authors of this communication acknowledge how much they owe to their German teachers of surgery.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED JANUARY 16, 1886.

Sawtelle, H. W., surgeon. To proceed to Los Angeles and Wilmington, California, as inspector, January, 1886.

Godfrey, John, surgeon. To proceed to Chattanooga, Tenn., and Rome, Georgia, as inspector, January 8, 1886.

Poison in Georgia.

A new law in Georgia enjoins that poison must be put up in scarlet wrappers, and the bottles labeled with paper of the same color, the printing to be in white letters. "Of all the hard papers to find in market," says a wholesale druggist, "scarlet is the most difficult, and printers say they cannot print in white upon such a surface. The lawmakers have hit upon an extremely difficult problem for the druggists."

A New Medical Battery.

We learn that a new medical battery has come out, in which the authors use lead in place of zinc, as the positive element, which is easily reducible from most of its compounds. As the negative element they employ a conductor, preferably of lead or carbon, coated or kept in contact with a layer of peroxide of lead.

Cost of Small-pox to Tennessee.

From replies to an inquiry sent by the State Board of Health to the health officers of the several locations in which small-pox appeared in the State during the past five years, it was ascertained that the cost had been nearly $60,000.

Items.

—A sanitary convention is to be held at Howell, Michigan, under the auspices of the State Board of Health, on Wednesday and Thursday, March 3d and 4th.

—The Austrian Minister of War has ordered compulsory vaccination with calf lymph for the whole of the Austrian Army. The order will be carried out with all expedition.

—M. Pasteur has, in a courteous letter, acceded to the application of the Hungarian Government, which had asked him to receive a Hungarian doctor, to be nominated by the State, as a student of his inoculation system.

—The first official recognition of female medical practitioners has just been made by the Italian government. The recipient of this distinction is Signorina Terne, M. D., whom Queen Marguerita has appointed one of her physicians in ordinary.

—The 500th anniversary of the foundation of the Heidelberg Unlversity will be celebrated next August. The celebration will be held in a hall specially constructed for the occasion, capable of holding 5,000 persons.

—The Medical Society of the District of Columbia at its annual meeting elected Dr. C. H. A. Kleinschmidt president, Dr. John B. Hamilton and Dr. W. H. Taylor vice-presidents, Dr. Thomas McArdle secretary, and Dr. C. W. Franzoni treasurer. The old board of examiners were re-elected, with the addition of Dr. Raymond T. Holden.

—There has been quite a serious epidemic of typhus fever in the Albany Penitentiary, and among its victims was the resident physician, Dr. Joseph W. Reilly, who died at his home in West Troy, January 15, after two weeks' illness. Between December 1 and January 11, seventeen of the inmates died from the disease.

—Leopold von Ranke, now more than ninety years of age, presents the anomaly of a man who has never taken any physical exercise, and is yet in perfect health. The great German historian has almost lived in his library, working for fifteen hours a day, and he has laid out more work which he hopes to complete before his one hundredth birthday.

—Dr. S. A. Defoe, of Washington, N. J., writes to the *Med. Record* that he has found the following to give excellent results in melancholia. ℞. Valerianates of zinc, quinine, and iron, each twenty grains, to be divided into twenty pills. One pill is to be taken three times a day before meals. The drugs should be absolutely pure. Dr. Defoe says he has tried this remedy thoroughly, and finds it a specific for the worry of nervous women and for incipient melancholia.

—At a recent meeting of the Biological Society of Paris, M. Brown-Séquard related some experiments he had made, by means of a special instrument, to determine the movements of single muscles in the body after death. He had found that there was a very considerable degree of contraction and relaxation, as much, for example, as 2½ mm. in a muscle measuring only six millimetres in length. He thought that the results of his experiments disproved the theory of coagulation in the muscular tissue as the cause of cadaveric rigidity.

—A London paper says that an apothecary of Thorndale had just received a fresh supply of vaccine points, and some of them happened to be exposed to view on his counter. A burly farmer from that neighborhood was in at the time, and amused himself by using one of the points as a toothpick, pricking his gums in the operation. It "took" in the most approved style, and the man is now in possession of a mouth that is crowding all the other features of his face out of shape.

—An investigation by the medical examiner shows that the recent sudden death of the Yale student which was attributed by the physicians to heart disease, and by others to over-exertion in foot-ball practice, was more probably caused by injuries received in an impromptu wrestling match. The examiner found that on the day of his death, the young man had a friendly scrimmage in his room with some friends. In the scuffle he was thrown violently to the floor. This shock, it is thought, caused the blood-clots in his brain which shortly after resulted in death.

—An International Committee at Nice, in the interest of the abolition of gambling at Monte Carlo, has prepared a memorial to Prince Charles III., of Monaco, in whose personal interest the gambling establishments are maintained. In this memorial is included a list of the suicides at Monte Carlo since 1878, all of them being due to disappointment at play, as an immediate cause. The list, which is explicit in names, dates, and other particulars, embraces, for the eight years, eighteen hundred and twenty persons.

—The adoption of the new rules of the House of Representatives abolished the Public Health Committee, and hereafter matters pertaining to the public health will receive no special attention in the lower House. It was held that the matter of public sanitation properly belonged to the several States, that governmental aid in time of epidemics did not require a special committee to adjust it, and that quarantine very naturally found its place of consideration in the Commerce Committee.

MARRIAGE.

WALTON—GROVE.—January 7, 1886, Levi S. Walton M. D. (Jefferson Medical College, Class '85), of Tullytown Pa., and Miss Flora Grove, of New Britain, Pa.

JENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle, pleasantly flavored. Retail $1.00. All of it pure pepsin.
See page 10.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin*," must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also affirmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Lecture.

THE TREATMENT OF VOMITING.

A CLINICAL LECTURE BY DR. DUJARDIN-BEAUMETZ,

Of Paris, France.

(*Concluded.*)

You may also make trials of Lasegne's remedy, who was in the habit of ordering in these cases tincture of iodine in the dose of from five to ten drops in a little sweetened water. In a recent thesis, Dr. Olli has shown that this remedy may be beneficially tried in all forms of dyspepsias with vomiting. In England they employ creasote, which, since the labors of Bouchard and Gemberd, has been very much given in pulmonary complaints, and may be administered in wine or in capsules mixed with oil. It is a medicine which may be sometimes advantageously tried.

You may also have recourse to a measure which has given me some success, and which has been recommended by Lublesky, of Varsovia. This physician, who had previously published several memoirs on pulverizations of ether, and shown the advantages which might be derived therefrom in chronic affections, has conclusively shown that the same method may give good service in vomiting from whatever cause. With a hand atomizer, like that of Richardson, for instance, you can spray the region of the stomach with ether for three or four minutes, and then make the patient eat a little food.

In the case of one of my patients who had almost incessant emesis, I obtained by this means a notable diminution in the number of vomitings. These pulverizations are attended with no inconvenience. Certain Spanish physicians, and in particular Gulceran and Rodrigues Mendez, have employed these sprays with success.

There is another simple expedient advised by Gros, namely, tobacco smoking. Having remarked that one of his lady patients, who was pregnant and suffered from incoercible vomitings, experienced marked relief when in a room that was full of tobacco smoke, the idea suggested itself to him of recommending this patient to smoke; she did so, and her vomiting entirely ceased.

Make use, then, of all the means that I have indicated; add injections of morphine, lavements of chloral, inhalations of oxygen, which Hayem considers as one of the best remedies in dyspepsia with vomiting, and which Penard has applied to the treatment of the vomiting of pregnancy; resort also to "gavage." Sometimes you will attain your end, at others you will fail, and you will then be obliged to have recourse to dilatations of the neck of the womb, suggested recently, or to premature delivery, which obstetricians have unanimously consented to employ if medicinal means fail.

By the side of these vomitings of pregnancy, I must place those which hysteria determines, and which, like the preceding, are characterized by a persistency which often defies all therapeutic means.

Apropos of these hysterical vomitings, I must make a distinction. In certain neuropathic patients you will see supervene veritable crises of vomiting, and of gastralgia, and for months the patient will tolerate hardly any food; then the gastric form disappears, to give place to other nervous trou-

bles. Nothing in the examination of the patient will reveal to you the cause of these vomitings. The uterine functions are well performed, the urine is abundant and voided without difficulty, and one can invoke in explanation of these disorders only the nervous state to whose influence the patient is subjected; this is the so-called nervous vomiting, to which I shall have occasion again to return when I come to the treatment of hysteria.

Against these vomitings, which belong to the groups of affections which Huchard has very happily characterized by the name of gastric hysteria, you can employ two orders of remedies which have given me excellent results, namely "gavage" (or forced feeding) and electricity.

It is especially in hysterical patients affected with spasmodic troubles of the pharynx and œsophagus, that the method of "gavage" succeeds; and a patient who is in the habit of vomiting all her food immediately after its ingestion, finds that these vomitings cease when the food is introduced by the stomach-tube. You may employ as a nutrient the meat-powder and milk before spoken of; you can also precede each "gavage" by a lavage. I have by this method obtained results which were truly marvelous, such as Charcot and Geoffry have also obtained. But in other cases this method becomes insufficient, and notwithstanding the gavage the patient vomits still; it is then that recourse should be had to electricity.

It is to Apostoli that we are indebted for the rules of the electrical treatment of vomiting, and you have often seen him in my hospital apply his method with success. This method consists in the positive polar galvanization of the right pneumogastric. The positive electrode is placed just outside of the inner extremity of the clavicle, in the point marked by the depression caused by the interval between the two inferior fasciculated origins of the sterno-mastoid muscle; this electrode, which is moistened, should be of small dimensions; the negative electrode is held in the hand of the patient. The battery which is used is that of Gaiffe, with "collector," and the quantity of electricity employed varies between ten and twenty milliamperes. As for the duration of the séance, it is very variable, and one ought not to cease the application of the electricity till the patients find their sensations of spasm and vomiting gone.

You may also employ direct electrization of the stomach with the apparatus of Bordet. You will follow here the same procedure as that which I described to you in a previous chapter under the head of dilatation of the stomach; only it is the positive pole which must be placed inside of the stomach, the negative electrode being applied over the walls of the abdomen. Moreover, it is the constant current which you will use, and not the interrupted. To forced feeding and to electricity you may join the use of prolonged baths, which sometimes succeed, as Ferrand and Douchez have shown. The duration of these baths is from three to eight hours, and the temperature from 68° to 82° F.

In other cases, vomiting in the hysterical is symptomatic of another pathological condition; the urine is not secreted, and this hysterical anuria, which Charcot has mentioned, and of which Fernet, Juventine, and Seconet have given examples, is accompanied with more or less abundant vomitings, in which urea in variable quantity is found. These vomitings resemble those of urinous dyspepsia. The latter is, in fact, almost always a dyspepsia with vomiting, and it results from a damaged state of the kidneys. As soon as these glands cease to perform their functions, the urea and excrementitious matters of the urine, retained in the blood, seek elimination by the intestines or by the stomach. The patient urinates, as it is said, by his stomach, and this it is which explains the frequency of the vomitings which accompany the nephritis, and in particular interstitial nephritis. The treatment ought here, of course, to be different; we are not so much concerned with combating the vomiting as in restoring the secretion of the kidneys by the exhibition of suitable diuretics, and when medical means fail, you will find yourselves powerless to arrest these vomitings, which supply the place of a function which is no longer performed.

In patients affected with urinary complaints, who incompletely empty their bladder, you will often see attacks of vomiting supervene, and it is one of the most common signs of the digestive trouble which afflicts this class of invalids. These vomitings are of a very persistent character, are often even provoked and augmented by all attempts to interfere with or control them, becoming absolutely incoercible.

In pulmonary affections, vomiting is an incident which is sometimes followed by grave consequences by preventing alimentation. This is what happens in young children, in whom the mechanical act of vomiting is so easy. The convulsive cough of pertussis provokes vomiting, which if the paroxysms are very frequent, may be so

numerous that alimentation can no longer go on; the patient wastes away, and may succumb to an intercurrent disease, facilitated by the gradual debilitation. This condition in pertussoid patients demands careful attention. The little patient must be fed regularly, in small quantities, and is sometimes benefited by sips of strong coffee, cognac, or some other alcoholic stimulant which promotes digestion; foods should be given which are rapidly and easily digested.

Phthisis in the first stage gives rise to vomitings which are more or less frequent. In his thesis, Dr. Varda, of Smyrna, one of my pupils, has shown that these vomitings are due to several causes, the principal of which are the dyspepsias, the intensity of the cough, compression of the pneumogastric nerve, etc.

But whatever may be the instigating cause of gastric troubles in the phthisical, they are tributary to one and the same medication, namely, to "gavage." In fact, by a circumstance the physiological explanation of which is lacking, while foods introduced by the mouth are vomited, those which are conveyed to the stomach by the flexible tube are well tolerated; and when I come to speak of the treatment of phthisis, I will show you all the benefits which you may derive from Debove's method.

As to vomitings due to cerebral affections, if from a clinical point of view they present a great importance, they have little interest therapeutically, unless from the fact that there is so little that can be done to relieve them.

Finally, gentlemen, do not forget that there are certain obstinate vomitings which may be cured by the simple application of a truss; this is the case with vomitings caused by certain hernias, either of the stomach or omentum, and which sometimes protrude through the linea alba over the gastric region, and may become irreducible.

Such, gentlemen, are the considerations which I desire to present respecting the therapeutics of vomiting. I have dwelt especially on certain aspects which you will be most often called upon to treat.

—The two chief Russian medical weeklies, the *Vratch* and the *Russkaya Meditsina*, just received, present their readers with pictures of a large stone "Memorial" which has been erected to the memory of 531 medical officers who fell in the war with Turkey during 1877–78. The site of the monument is the Alexander Place, Sophia. It is stated that a similar erection is contemplated in the Caucasus.

Communications.

THE DIAGNOSIS BY AUSCULTATION OF PERICARDIAL FRICTION MURMURS.

BY E. T. BRUEN, M. D.,

Assistant Professor of Physical Diagnosis, University of Pennsylvania; one of the Attending Physicians to the Philadelphia Hospital.

The differential diagnosis of pericardial murmurs by means of auscultation is often a problem of the greatest intricacy, owing to the failure to recognize certain laws which pertain to the foundation of the auscultation of cardiac sounds and murmurs. In studying any case of possible pericarditis with equivocal murmurs, it is always helpful to decide whether the etiological relations in a case favor the presence of pericarditis. This condition is rarely, if ever, present as a primary process, but it is frequently consecutive upon rheumatism or with alterations of the blood-tissue, such as exist in renal processes, pyæmia, or it is secondary to acute or chronic inflammations in adjacent structures, such as the pleura, the peritoneum, the perihepatic tissue, and the mediastinal region.

The special object of this article is to direct attention to the differential diagnostic features of pericardial frictions in general, but especially of those varieties which acoustically closely resemble endocardial valvular murmurs.

In reviewing the causes which produce pericardial murmurs, Hayden has written of acute pericarditis: "I have never met with a case which would warrant me in asserting that a state of simple dryness and vascularity of surface may give rise in the pericardium to veritable friction sounds. I do not, however, deny the possibility of an occurrence which theoretically would seem not improbable. In every instance, without exception, in which I have had the advantage of determining by post-mortem examination of the body, the condition of the serous surface of the pericardium where friction sounds of indubitable pericardial origin had existed during the patient's last illness, I have found lymph in greater or less quantity effused upon the surface." Da Costa supports this statement, and theoretically grants that the initial stage of dryness of the pericardial membrane is associated with murmur, but adds that "practically, I have never seen it, and in the suspected cases, lymph has always been found, with the single exception of a case in which the friction sound had disappeared nearly a week before death, which re-

sulted from kidney lesion, and where it was reasonable to infer that the lymph had been absorbed."

The attributes of a pericardial friction murmur are its quality, including loudness and pitch; its point of maximum intensity; the area of its diffusion, and its rhythm.

1. It is indubitable that the quality of pericardial friction murmurs may be distinctly rubbing or friction-like, and synchronous with the movements rather than the sounds of the heart, which characteristics lead Watson to assign the designation of to-and-fro murmur; but it is equally true that pericardial murmurs are sometimes blowing in quality, and quite indistinguishable acoustically from the endocardial valvular murmurs. The superficial quality of the former murmurs affords a basis of distinction, while intra-cardiac valvular murmurs are audible, as though produced on a different and deeper plane. The rubbing sound will be apparent until the quantity of fluid becomes sufficient to separate the walls of the sac; the friction sound reappearing when the lymph is absorbed. The gradual disappearance of the murmur with a gradual reappearace is a fairly diagnostic sign.

The friction murmur may also be recognized by palpation. Stokes, indeed, looked upon the friction fremitus as separating pericarditis from valvular disease. A true pericardial friction fremitus is not limited to the known positions of maximum intensity of endocardial murmurs, but it may be felt over the præcordia, but not often beyond the normal limit of cardiac dullness, unless there be associated inflammation of that portion of the pleura adjacent to the pericardium.

2. If it is granted that in cases of acute pericarditis the murmur is usually due to roughening of the pericardial surface by the presence of lymph, it becomes inferential that the continuous pulsation of the heart may reduce the roughnesses at one point of the pericardium, while fresh areas of roughness may be developed, and consequently the acoustic phenomena must vary, viz., the point of maximum intensity of the pericardial murmurs cannot always be the same. The friction murmurs must also cease if the fluid effusion becomes considerable, or adhesions of the pericardium may modify or entirely prevent the development of friction sounds. Occasionally bands of lymph have been found on post-mortem examination, stretched like a bridle over the heart across the pericardial sac, which must have favored the development of a murmur during life. When local adhesions of the pericardium permit portions of the free surface, more or less covered with lymph, to exist, the heart being free to move, friction sounds can occur which may be most intense anywhere over the præcordia, except at the points of adhesion. It is evident therefore that the location of maximum intensity must be a variable or shifting point, affording a conspicuous contrast to the organic valvular murmurs, which have fixed centres of maximum distinctness, corresponding with a point at which the chamber of the heart where the murmur is produced, approaches most closely the chest surface. The usual location of friction murmurs, however, is over the heart or near the orifices of the vessels.

3. Special attention should be given to the area of diffusion of pericardial murmurs. It is an ordinary distinctive point that in endocarditis the abnormal murmurs are transmitted upon definite lines of maximum intensity; but in pericarditis one may recognize a very loud murmur, possibly simulating in quality an endocardial murmur, and yet its area of diffusion with maximum intensity is commonly limited to the præcordia, or if transmitted over the whole chest, as may happen in children, or in adults with cardiac hypertrophy, the area of maximum intensity of diffusion will follow some line which does not correspond with the area of diffusion of endocardial murmurs. The latter are transmitted with maximum intensity in a line which coincides with the direction of the blood current by which they are produced. Indeed, by closely observing this single point it may be possible to differentiate in the same case between pericardial and endocardial murmurs, as was illustrated by a recent autopy upon a case in the Philadelphia Hospital. Lesions were found which had caused a double aortic and double mitral murmur, and also a pericarditis with adhesions which had given rise to pericardial friction murmurs. In this instance all these murmurs had been correctly analyzed during life.

4. The rhythm of pericardial frictions has been already noticed as to and fro, and synchronous with the movements rather than the sounds of the heart, yet the rhythm of pericardial friction murmurs may be systolic or diastolic.

5. A change of posture may increase the intensity of a pericardial friction murmur, rendering a murmur which is faint in the vertical quite distinct in the recumbent position, while in endocardial murmurs usually the reverse prevails, that is, in those cases in which change of posture has any effect upon

the acoustic phenomena of endocardial murmurs.

6. It should be borne in mind that certain postures give relief to the dyspnœa of pericarditis when this symptom is prominent; for instance, if the recumbent posture on the left side is selected, the liver and heart both tend to exercise pressure on the pericardium, so that the posture on the right side is usually preferred. This symptom has, therefore, a relative value in estimating the etiology of a doubtful murmur.

7. The alterations common to the walls of the heart in encocardial valvular disease are absent, unless, indeed, endocardial processes are also combined.

In recognizing cases of endocardial murmur, we can estimate the gravity of the lesion rather by the changes in the auricle or ventricle of the heart than by the diffusion or quality of the murmur; but in pericarditis, these changes do not correspond with the hypertrophy and dilatations commonly found in endocardial valvular lesions; and when in uncomplicated chronic pericarditis, with adhesions, the heart is hypertrophied, the organ is apt to be drawn up to the left by the adhesions in a more or less significant manner.

8. Friction murmurs can be developed by the movements of the heart in the pleura adjacent to the inflamed pericardial sac, if the former be also covered with lymph. One of the best methods of differentiating this murmur from one developed within the pericardial sac is to cause the patient to cease breathing for a moment, and then by ausculting the heart the friction-sounds persist if of pericardial origin. If the portion of the pleura adjacent to the pericardium be also covered with lymph, the heart's motion transmitted through the pericardium may produce pleuritic friction even while the lung is at rest. The location of the murmur at the border of the pericardium and its transmission beyond its confines will be the best aids to auscultation; since, in pericarditis without associated pleurisy, the murmur will more probably be confined to the normal limit of cardiac dullness, and the same rule will apply to a friction fremitus recognized by palpation.

A friction murmur can also be produced by the action of the normal heart in an inflamed and roughened pleura. This is very difficult to recognize with precision; the foregoing principles can be applied, and the etiological relations of the suspected conditions studied. The murmur is often perceived near the apex of the heart. It may not occur with each cardiac pulsation, and may cease during held expiration.

These observations might readily be extended to include other methods of physical diagnosis applicable to the recognition of pericarditis; but the subject is a familiar one, and only the survey of the results of auscultation has been attempted, chiefly to bring out the characteristics relating to the focus of maximum intensity and the area of diffusion of pericardial friction murmurs.

A CASE OF PERITYPHLITIS WHICH WAS APPARENTLY RECOVERING, BUT WHICH IMPERATIVELY DEMANDED OPERATION AS EARLY AS THE SIXTH DAY.*

BY W. W. KEEN, M. D.,

Senior Surgeon to St. Mary's Hospital, Philadelphia.

George G., æt. 22, shoemaker, of Vineland, N. J., a spare young man, in good general health till Sunday, September 27, 1885. On the previous evening he had eaten very freely of grapes, but went to bed in his usual health. On Sunday evening, the 27th, he was suddenly seized with intense and excruciating pain in the right iliac fossa. Supposing it to be an ordinary colic, he took considerable ginger; but finding no relief, he sent for Dr. Wiley, his usual physician. Dr. Wiley, recognizing the character of the attack, at once applied hot fomentations and administered a hypodermic of morphia.

Though partially relieved his pain continued, with fever, a pulse of 120 to 130, constant bilious vomiting, great tenderness in the right iliac fossa, and dullness over a space as large as the hand. His right leg was not flexed. He had had no chill. His highest temperature was 102.4°; it began to fall October 1st, the fourth day. Opium was used continuously, from 3 to 8 grains daily.

On October 3d, the sixth day, I was asked by Dr. Wiley to see him with a view to operating. I found him in bed, with his legs extended, the belly not markedly tender, and he was generally comfortable. He could turn in bed, and move the right leg without suffering, and was not in much pain. His pulse was 88, and the temperature was 99.4°. He breathed easily. In the right iliac fossa there was a perceptible increase of resistance, with doughiness, but no well-defined tumor. The dullness was not well marked, except on

* Read before the Clinical Society of Philadelphia.

deep pressure, which did not cause much pain. No fluctuation could be detected. There was considerable œdema of this region. A small right oblique inguinal hernia had existed for years, which Dr. Wiley had reduced before I saw him. There was no tenderness in the hernial region, so that I rejected the idea that the hernia had anything to do with his present condition. The vomiting also had ceased, and it should also be remarked that it had at no time been stercoraceous. His bowels had not moved for a week.

The marked amelioration in his general condition, the abatement of the fever, the decrease in the local signs, such as pain, tenderness, and swelling, the absence of chill and fluctuation, all led to the supposition that the attack was probably passing away, and that the wisest course would be to wait. The only signs of evil were the presence of the obscure tumor, the doughy feel, and the local œdema. The tumor might be inflammatory, or it might be caused by a collection of pus. To determine which of these conditious existed, and thereby to determine whether an operation should be done, resort was had to the hypodermic needle. This was filled with pus at the first attempt, and the operation was at once determined upon.

The usual operation was done by an incision parallel with Poupart's ligament, and about three inches in length. Thorough antiseptic precautions were practiced (including the spray), carbolic acid being used. Several small vessels required catgut ligatures, and the hypodermic needle was used twice as a guide to the seat of the pus. When the cavity was reached, a gush of pus occurred. The entire amount that escaped was estimated at nearly a pint. No grapeseed was seen, but it might readily have escaped observation in the pus. The odor of the discharge was offensive in the extreme. The cavity was washed out with the five per cent. carbolic solution until the solution flowed clear; a drainage-tube was inserted, and the wound was dressed with a large mass of antiseptic gauze, in order to absorb the expected abundant discharge.

The subsequent course of the case was favorable in the extreme, and the treatment was very simple. The same dressing was continued. The diet was purely liquid. The bowels were moved by enema on the seventh day. The drainage-tube was kept in for four weeks, but was shortened from time to time, as required. The temperature did not rise above 99° at any time after the operation. The pulse was 84. In about six weeks the wound was entirely healed, and by the end of November, some seven to eight weeks after the operation, he resumed his usual work.

To the late Dr. Willard Parker is due the credit of formulating and establishing the operative treatment of perityphlitis. Previous to 1867 the treatment was almost exclusively an expectant medical treatment. The present case is a marked evidence in favor of the now generally favorable estimate of the operative treatment in suitable cases, due to the diffusion of his ideas. The noteworthy points in the case are the apparent convalescence masking the abscess which was present, the value of the hypodermic needle as a means of diagnosis, and the early date of the operation.

All of us have seen many cases the counterpart of this, in which recovery has taken place without suppuration. In these cases the inflammatory hardness continues after the subsidence of the initial fever, and only disappears gradually, and after a long period. Apart from the evidence of the needle the present case seemed, both by its symptoms and its physical signs, probably to be of this character. Earlier than the fifth day the presence of pus is unusual; but as Parker and Burger have shown, and is now emphasized, after this time it should be suspected and sought for; for if it exists, its presence is a serious menace for the future. True, it will escape either externally (the least favorable course), or by finding its way into the bladder, rectum, or vagina. But such a method of escape is fraught with danger, and should be averted if at all within our power. The simple (and of course not novel) expedient adopted in this case, where the decision as to the operation rested almost wholly upon the verdict of the syringe, is one to which I wish to call especial attention. It is within the reach of every one; it is free from danger, and should never be neglected. If at the first puncture no evidence of pus is found, the needle should again be used at a neighboring point; and thus several punctures may be made on the same or on successive days, till we are sure that no pus exits, and therefore the hardness and dullness are inflammatory and not due to pus.

The earliest operation recorded is, I believe, on the fifth day. In the present case it was done as early as the sixth day, and yet a pint of pus was found. No better evidence is needed to show the value of the early search for pus; and if found, its immediate evacuation by operation is the only rational course.

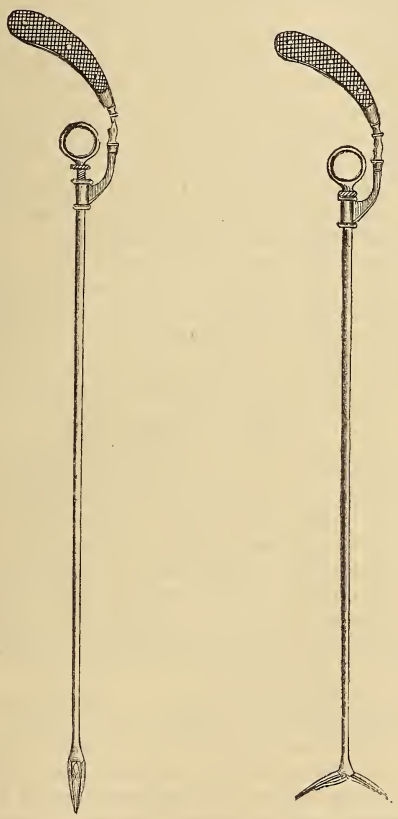
AN IMPROVED BULLET-EXTRACTOR.

BY W. J. HOFFMANN, M. D.,

Of Washington, D. C.

The accompanying illustration represents an instrument for the extraction of bullets from deep-seated localities in the human body, as well as for the removal of foreign bodies from the trachea and œsophagus. For the latter, the contrivance is either curved or it may consist of a flexible steel rod with a tube constructed of a spiral band of steel.

The instrument consists of a tube one-fifth of an inch in diameter, and fourteen inches in length (or more if desired), armed at one



end with two blades, closely resembling a serpent's jaws. To the opposite end is attached a handle. A steel rod passes through the entire length of the tube; a ring for manipulation being attached at the rear end, while at the opposite extremity are secured, by means of a slot and pin, two slightly curved arms which connect it with either blade. By pressing the ring forward, the blades are opened, closing them being effected by drawing it backward. The extremity of one of the blades terminates in a short tooth, directed inwards, the opposing blade being armed with two between which the former enters, presenting a smooth rounded surface when closed and ready for introduction.

The present instrument is a slight modification of one devised by the writer in 1870, while attached to the Prussian medical corps (during the Franco-German war of 1870–71), when it was employed with great success, and in numerous instances in which the then available bullet-forceps entirely failed. The Turkish government recently adopted the above-mentioned instrument, and the writer had the honor of being appointed to supervise the manufacture of a sufficient number for immediate use in the present campaign.

Mr. Charles Fischer, of Washington, D. C., is the manufacturer.

Hospital Reports.

PHILADELPHIA HOSPITAL.

Service of Dr. W. H. Parish.

Cancer of the Cervix.

This woman, aged 58, has had several children, and passed through the menopause as usual. Four years after the climacteric, she commenced to have bleeding from the uterus, which was the first symptom of her present trouble, and for which there was no apparent cause. After lasting for some weeks, this hemorrhage was supplanted by a moderate watery discharge, which gradually became offensive. For some months there was this variation, the discharge being sometimes watery and sometimes bloody. She began to lose flesh and her color to change, she becoming very sallow; so that there were strong reasons to suspect carcinoma. In fibroid tumors, however, we may have an offensive discharge, and hemorrhage may occur. I find, upon digital examination, that the cervix is enlarged, rough, and very friable, bleeding upon the slightest touch, and I note that there is a growth from the cervix, not from the inside of the organ. The disease has gone too far for us to take into consideration the propriety of removing the whole uterus, or even any very considerable portion of it; it has progressed so far that a cure is out of the question, and we can only hope to palliate. As a rule, pain

is not an early symptom of cancer of the cervix, as it used to be said.

I will remove a portion of this mass with the wire and curette away the rest. I find it so soft that by merely pulling on the wire the mass comes away in fragments. I will swab the surface with vinegar, which is antiseptic as well as astringent; it will not irritate, stain, nor give us the annoying coagula that are produced by Monsel's solution. One or two sponges, saturated in vinegar, I will leave in the vagina for a while. The probabilities are that after this operation, there will, for a time, be less hemorrhage and discharge, which will render life more pleasant, and make this woman less of a nuisance to those about her. We must be careful after performing such an operation not to go to a parturient woman until we have disinfected our hands with corrosive sublimate, for such discharges will be very apt to convey child-bed fever.

After the vinegar sponges have been in for twelve hours, they will be removed, and the vagina syringed out with Platt's chlorides, one part to ten of water, injected twice daily. Sometimes these cancerous masses will form adhesions to and ulcerate into the bladder or rectum, forming one large cavity common to all, and, of course, producing incontinence of both urine and fæces.

The question of the advisability of the removal of the whole uterus for cancer is still *sub judice*, but, in my opinion, it is only justifiable in the very early stages of the disease, at which time the affection is very rarely recognized.

Bloody Urine in Pregnancy.

I have here a pregnant woman who passes blood in her urine, both as streaks and intimately mixed with the urine. I once had a patient (pregnant) who passed between a pint and a quart of pure pus; upon previous examination two tumors had been found, one on each side; in one was the fœtus, and there was fluctuation in the other. At first it was thought to be an ovarian cyst, but after the passage of the pus it collapsed. After the cessation of the pus in the urine, this tumor became again apparent. Labor finally came on, after which there was a high temperature, and the patient died. An autopsy was not allowed, but I am quite sure that there had been an accumulation of pus in the pelvis of the kidney. Ovarian tumors may form adhesions to the bladder, and suppurating, open into and discharge pus into that viscus, giving us the phenomena of purulent urine.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. Theophilus Parvin.

Uterine Fibroids.

This woman, gentlemen, is said to be suffering from sub-mucous fibroids. She is thirty-six years old, has been married ten years, and has had no children. Now, this sterility is not due to an inability to conceive, for the woman has had several miscarriages, from which I conclude that the sterility in this case is due to some condition of the lining membrane of the uterus that renders it unfertile soil for the product of conception. Now, sterility is a not infrequent consequence of uterine fibroids. They cause catarrhal and congested conditions of the endometrium, which is relieved by hemorrhagic discharges, which wash away the product of conception. In this case we have the history of a profuse flow after each miscarriage. I find the cervix is unchanged. I feel a hard mass in the supra-cervical portion of the vagina, which seems continuous with the cervix, but the abdominal muscles are so rigid that I cannot say, with any degree of certainty, that I can feel the fundus or a tumor above it.

Now, when we have fibroids that cause uneasiness by producing hemorrhage, we can have no better remedy than the hypodermic use of ergot. I would inject from twenty to thirty drops of the fluid extract of ergot into the hypogastrium, or directly into the tumor, if it be accessihle. We might inject five or six drops of Fowler's solution into the tumor, but this latter is very uncertain, and will disappoint our expectations in one-fourth of the cases where it is used. The next step would be dilatation of the cervical canal. If the alarming conditions still persist, then we must enucleate the tumors. But this is a dangerous operation, unless they are clearly pedunculated, hence it should be undertaken only as a last resort.

Hypertrophic Elongation of the Cervix.

Dr. Emmett seems to believe that there is no such thing as true hypertrophic elongation of the cervix; he considers that all such cases are merely apparent, and are, in reality, merely a pulling down, as it were (as you might pull out putty), of the cervix from its own weight. Now, I am quite sure that there is such a thing as true hypertrophy, and I am quite sure that we have this condition in the case before us, where the vaginal cervix measures three inches, while, normally, it should not be more than half an inch. In such cases, of course, we can only afford re-

lief by amputation. This is in some respects a simple and satisfactory operation. The cervix should be split into two lips, as it were; above the point at which we propose to amputate, we should pass several stitches through each lip; then, after amputating, we should draw down the threads and tie them together. Thus we unite the mucous membrane, get union by first intention, and avoid the danger of the two sides agglutinating and causing stenosis. Besides, if we allow the wound to heal by granulation, the process is much slower, the danger of sepsis greater, and the general results less satisfactory. If you find the fundus in its normal position, and the cervix away down at the vulva, you know that you have either stretching out or hypertrophy. For the purpose of amputation you may use either the galvano- or thermo-cautery or knife, or the ecraseur. Secondary hemorrhage is a contingency to be dreaded in these cases, while the primary hemorrhage may be quite severe: I have known one death from each. On the whole, I prefer using the scissors for this operation, but I would not use them in cancer, save where it was strictly limited to the neck. In eighty or ninety per cent. of all cases of uterine cancer it is not limited to the neck, but has a decided tendency to extend upwards and implicate the body of the organ. You will sometimes be surprised to see how far up it has extended, when you had supposed that the cervix alone was involved.

The Sexual Passion.

As bearing on the case of nymphomania about which I lectured to you last week, I wish to say a few words about the very prevalent notion that cantharides excites the sexual passion. It not infrequently occurs that this drug is given to young girls for the purpose of causing them to desire intercourse. In ancient times it was believed that a diet of fish stimulated the sexual organs, which idea originated from the fact that Venus was born in the sea. Now, while cantharides will most likely produce genital erethrism in the male, there is no positive case on record where it has produced this effect in the female; I will admit that it is barely possible that such might occur. Again, it has been claimed at various times that certain drugs possessed the power to diminish or hold in check the sexual passion, and for this purpose it was once the custom in Europe to administer to nuns an infusion of white water-lily, which was supposed to destroy all sexual desire. Camphor was also believed to possess this power, and one hundred and fifty years ago in England the women were accustomed to wear camphor about their necks as amulets to preserve their virtue. This came out in a trial for rape, where it was contended that a man had forcibly carried off a girl in a carriage. It came out in the trial that during the journey in the carriage, at one stage, the girl opened the window of the carriage, and also opening the bosom of her dress, removed the camphor from her neck and cast it from the window, which was held to be an act of submission on her part. Of course, the idea about all these drugs is very vague; it is a vague notion to talk about exciting or repressing sexual passion by drugs. If we have any special sedatives, they are to be found in the alkaline bromides and also in the bromide of camphor. These drugs may be used in the treatment of masturbation and nymphomania; but as I have already told you, the most radical treatment will consist in the removal of the cause. In the majority of cases this cause is not to be found in the sexual organs, but in some impure thought planted in the mind in childhood, that has matured and borne most terrible fruit. Therefore the mind must be controlled; moral suasion, and not drugs, must be relied on to work a cure.

Flatulency.

Here is a valuable case, for you will be constantly confronted with similar ones. This woman, who is forty-eight years old, and has had thirteen children, comes to us because her abdomen is enlarged. This is exceedingly common, hence the treatment will be of interest. For some time past her menstruation has been scanty, and it has not now recurred for six weeks. She suffers some from headache about the menstrual period. But she complains chiefly of this abdominal enlargement, which varies, being sometimes greater and sometimes less, and is especially noticeable about the menstrual epoch. The lineæ albicantes, as you see, are well marked, as we would expect to see them in a woman who has borne thirteen children. Now, what is the cause of this enlargement? I dip my fingers well into the abdomen, but I can detect no tumor; the whole abdomen is resonant, and she is costive. Well, gentlemen, this swelling is simply tympanites. Women will popularly speak of it as "bloating;" they will remark that their abdomen becomes bloated at the menstrual period. It is due to a partial paralysis of the intestinal muscles and a consequent accumulation of gas. To relieve this condition, we must increase

the vigor of the muscular coat of the intestines, which we can do by bathing the abdomen with cold salt-water, with subsequent friction. Remember that this abdomen has been relaxed by thirteen pregnancies, so that the abdominal walls even fail to give the usual support to the intestines. We must, therefore, use artificial support, which will be derived by a strong drilling or flannel bandage. In addition to these measures, we will give the woman a pill containing aloes (gr. $\frac{1}{3}$ to $\frac{1}{2}$), podophyllin (gr. $\frac{1}{10}$), extract of nux vomica (gr. $\frac{1}{3}$), and belladonna (gr. $\frac{1}{12}$), one, two, or three daily; much improvement will be noted in a week. These cases may seem trivial, but they are very annoying to the patients, and will call for relief.

Sterility.

Here is a woman who has been married for two years and a half, and has never been pregnant. She has had leucorrhœa for two years, and complains of backache. You will note that these women who complain of backache will tell you that they put pillows into the small of the back to afford relief. Instinct seems to teach them this. Shakespeare tells us, "Take some new infection to thine eye, and like rank poison the other will straightway die." I imagine this pillow custom rises from the endeavor to throw higher up a body that is pressing downwards. It is an unconscious invocation of the general law of gravitation. This woman comes to us mainly because she is sterile; she desires to have children. When you resort to bi-manual examination, always put the index finger of the left hand in the vagina, keeping the right hand free for the external work, that is, unless you are left-handed or ambidextrous; ordinarily there is more facility in the right hand. I touch the os, but this contact reveals nothing. When making a bi-manual examination, it is always well to have the woman's head somewhat elevated, that the abdominal muscles may be relaxed. I find the neck of the uterus nearer the symphisis pubis than it ought to be; I should find it about in the centre of the parturient canal, and about the middle of a line drawn from the iliac spines, but here it is only about half an inch from the symphisis pubis. Why is it so far pushed forward?—for it must be either pushed or drawn forward. Away up in Douglas's cul-de-sac, I find a hard mass about the size of a small apple. Now I am sure that there is either retroflexion of the uterus or a tumor in its wall. How can I tell which it is? I feel with my right hand above, and as I know that the uterus cannot possibly be in two places at the same time, I know it is not retroflexed into the hollow of the sacrum, because I feel it well up in the median line of the abdomen. Now, when I press on this mass through the posterior vaginal wall, I find it almost as hard as this table; it is altogether too hard for the uterus. In doubtful cases, where there is no suspicion of pregnancy, the sound must be passed. This has been done here, and it passes not into the tumor, but anterior to it; where the cervix seems fused into the tumor, there is an abrupt line of demarcation, which would not be the case if this mass were the uterus. Now knowing that a tumor is causing all the trouble, what shall we do? I have a case up-stairs similar to this, in which I have accomplished a great deal by gently, gradually, but persistently pushing the uterus upwards. A great deal can be done by this method, but you must be patient; you must not be discouraged, for your progress will be very slow. Remember the story of the man who was able to lift an ox; commencing when it was a little calf, he daily picked it up, and it grew so gradually, the increase of weight was not appreciated, and he was finally able to lift a full-grown ox. So day by day you can push the uterus up a very little at a time, and in the aggregate you will accomplish a great deal. The woman should be placed on her knees and face. and you should operate with two fingers, working for say five to ten minutes at a time, then allowing her to maintain the knee-face position for twenty to thirty minutes. The success by this method will sometimes be very great. Do not abandon this procedure until you have given it a very thorough trial, even though several weeks may elapse without any apparent benefit. When the uterus is well lifted up, it will add greatly to the comfort and safety of the patient.

Intra-mural Fibroids.

This colored woman, aged 42, has had no children, but she complains of abdominal enlargement, which seems somewhat most marked on the right side. Now what is this tumor? Is it physiological, or is it pathological? The tumor extends to a little above the umbilicus, and slopes off. At its summit it is not quite broad enough to be the fundus of the uterus. If it were a physiological enlargement of the uterus, we would have the involuntary muscular contractions, which are wanting; so also if it were so large physiologically, it would yield at some points, but it does not, it is very

hard; so also in such a case we ought to hear the fœtal heart-sounds (for it is large enough for the seventh month of pregnancy), but we do not. The cervix is found high up, is soft and pulpy; the sound passes one and one-half inches, then goes off to the right one inch, then forward one inch, and then backward one inch, giving the sensation of sliding over a lump. It is reported that she has hemorrhage every two weeks. Now Dr. Da Costa (not the professor), who has brought this case here, proposes to give the woman muriate of ammonia until he is satisfied that she has hemorrhages, then he will give her half-drachm doses of fluid extract of ergot or gossypium every four five, or six hours.

Metritis (Subinvolution).

Here is a woman who has been married for two years, and miscarried at three months one year and a half ago. She complains of pain in the sacral region that radiates to the inguinal region; her bowels are costive, and her menses regular. It is said that she has subinvolution. Well, you know my views about this doctrine of sub-involution. A uterus evolves; why does it not involve? Because there is some inflammation about it. It is not truly sub-involution, but it is metritis that we have to do with in these cases. There is a glairy, white-of-egg-like discharge from the cervix, which is very characteristic of endocervicitis, the discharge from the cavity of the uterus being more watery. Well, how will we relieve this condition? In the first place, we must lift the womb up and support it, so that its engorgement will be relieved; hot water injections will also aid this purpose. Then we will apply Churchill's iodine or carbolic acid, or the acid and iodine, to the cervix. Pressure will also aid us by diminishing the size of the uterus, by causing absorption of some of the excess of tissue. This compression we can accomplish by means of Hagar's hard rubber dilators. Hagar claims that in one hour we can dilate the cervix so as to admit two fingers; and this will be a good expedient in abortion, to enable us to remove the fragments.

—According to a recent parliamentary return of the total number of persons of unsound mind, not being British subjects, who were patients on the first of January last in any county or borough asylum, it appears that in England and Wales the number of such patients was 434, 287 males and 147 females. There were only four in Scotland.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Meeting October 22, 1885. The president, J. C. Wilson, M. D., in the chair.

Dr. J. Collins Warren read a paper on

A Comparison of the Changes in Arteries after Ligature, and in the Ductus Arteriosus and Umbilical Arteries after Birth.

After the ligature of an artery in continuity, the earliest changes noted are the formation of the thrombi within the vessel, and the development of a mass of inflammatory tissue or callus around the point of ligature externally. No perceptible cell action can be observed in the inner wall with low powers during the first week, although under favorable circumstances a proliferation, to a limited extent, of the endothelial cells near the point of ligature can be seen with high powers, and occasionally a few wandering cells may be found to have penetrated the walls of the vessel at the same point. In the second week the bundle of fibres of the adventitia, which were surrounded and held by the knot, have been absorbed, and the two ends of the vessel retract slightly from one another, leaving the ligature imbedded in and partly disintegrated by the granulation cells. The walls of each portion appear to form a complete *cul-de-sac*, and it looks at this time as if the healing process were complete; but it can hardly be said to have more than begun, as the vessel has not yet passed through what may be considered as the first stage of healing. The beginning of the second stage is marked by an unfolding of the ends of the vessel, the walls separating somewhat after the manner of opening of a bud, which permits the entrance of a considerable quantity of the granulation tissue. A disintegration of the thrombus follows, and we have now a fully developed external and internal callus, a small fragment of clot still protecting the latter from the current. The ligature may be totally disintegrated and absorbed, or it may have become encysted, or finally it may have created a small abscess about itself which has discharged the fragments of thread through a sinus opening externally. The second stage is completed when the internal growth has reached the neighborhood of a branch. After this we have an absorption of the callus, which, as in fracture, is only a provisional structure, and eventually the

two ends of the vessel are found held together by a slender cord of varying length. The walls of the vessel are slightly separated at each end by a cicatrix consisting of connective tissue externally, inside of which is another layer consisting largely of unstriped muscular fibre, the surface being covered within by a new endothelium. The cicatrix is always pierced by a vessel which terminates in a number of capillaries ramifying in the cord. We have here a scar made up of three layers resembling closely the three coats of the vessel.

In the large vessel of amputation stumps we have a somewhat different series of changes. Soon after the ligation, the end of the vessel may be seen imbedded in granulation tissue and containing a thrombus of varying length. By the second week there is a marked change in the intima, extending for some distance above the point of ligation, probably to the first large branch or to the origin of the vessel. Examined several months later, when the healing process has been completed, the vessel is found to be preserved in the form of a cord running from the first large sized branch to the cicatrix of the stump; on laying open this cord the walls of the vessel are found preserved, the interior being filled with new tissue, leaving spaces occupied by one or more vessels. There has been a process resembling that known as obliterating endocarditis, by which the calibre of the blood-channel has been narrowed to an extent to adapt it to the diminished blood supply. In this obliterating tissue we find comparatively large vessels, with new coats consisting of an endothelium, an elastic membrane, and also a new media. An erosion preparation would best represent the condition of the arteries of the stump at this time. The main artery would, after giving off its largest branches, break into a spray of smaller vessels, no one of which would predominate.

A comparison of these two modes of healing with the changes seen in the arterial system seen after birth, shows certain resemblances in the two processes. The ductus arteriosus, about the time of birth, differs considerably from the structure of the aorta and pulmonary artery. The media is much thicker than in either of these vessels, it is thrown into irregular folds which are increased at the time of birth and help to narrow its calibre. The distinctions between the different layers of its wall are less marked than in other vessels. The lamina elastica is indistinct, and in places apparently wanting; the media consists chiefly of longitudinal layers of muscular fibres, a few circular bundles existing in the innermost layer. A few weeks after birth a greater portion of the walls of the ductus undergoes hyaline degeneration, the inner or circular fibres of the media alone remaining, these being reinforced apparently by a growth from the media of the larger vessels. At this time there is an active growth of long spindle-shaped cells with staff-shaped nuclei; at the edges of the media bordering on the opening into the aorta, there is also a moderate thickening of the intima. Eventually the hyaline tissue becomes absorbed and is replaced by a ligamentous band of fibres, which becomes continuous at either end with the media of the larger vessels. At the aortic end, in a longitudinal section we see the media slightly separated. At the point of the cicatrix and between them, and also continuous with them, are the longitudinal fibres of the ligamentum arteriosum. In this ligamentous tissue and between the edges of the media are numerous new muscular cells; nearer the surface is a layer of thickened intima, which in the aorta has not only connective tissue in it, but also a deep musculo-elastic layer; in the centre of the depression marking the site of the cicatrix a small vessel is given off which penetrates into the axis of the ligament, where it either loses itself in a capillary network or becomes continuous with a similar vessel coming from the pulmonary artery. We have here conditions closely resembling those which have been described as existing in the cicatrix of a large artery after ligature in continuity, namely, the slightly separated ends of the media, between which lie the fibres of the ligament connecting it with the pulmonary artery, a new intima and a new growth of muscular cells, and finally a central arteriole. The only point of difference is the preservation of a layer of circular muscular fibres which form an outer wall to the ligamentous band, a much-needed support at a point exposed to great tension. Further protection is afforded by the oblique insertion of the ductus into the aorta, diminishing the pressure upon this particular point, at which the umbilical artery, or that usually called the hypogastric artery, the portion within the abdomen, at its origin from the internal iliac, is a vessel of considerable size, being in fact a continuation of that artery. At its termination in the umbilical wound it has greatly contracted, and is filled with clot for a distance of about one inch. The outlines of the various walls are not as distinct as in other vessels, and the elastic lamina for the most part wanting.

No special change is seen in the elements of the walls of the vessel except a slight accumulation of endothelial cells near the apex of the thrombus. A few weeks later there is a distinct growth on the inner surface of the wall up to its point of origin, the terminal portion having undergone a hyaline degeneration and obliteration for a short distance. The vessel has greatly contracted throughout its entire length, and its calibre is further diminished by the growth in its interior. Cross sections taken from the superior vesical artery in adult life show the media as a wall thick out of all proportion to the size of the vessel, and consisting not only of its original wall, containing longitudinal muscular cells interspersed with elastic tissue, but also an inner circular row of cells, which is provided with a well-formed elastic lamina. It seems probable that the greater portion of the hypogastric artery has been preserved, the ligamentous band which extends to the umbilicus consisting of the obliterated extremity of that vessel, much elongated during the process of growth. The series of changes which occur in the hypogastric artery after birth is closely analogous to that seen in the main trunk of an amputation stump—a slight portion of each vessel is destroyed, both retract and are attached to the terminal cicatrix by a band of fibrous tissue, both remain as pervious vessels with thickened coats and narrowed calibre. In both the process is not unlike that seen in the so-called obliterating or compensatory arteritis. Arteritis hardly seems a term applicable to the changes taking place in normal arteries after birth, nor can the alterations which have been developed through the whole length of a large vessel, extending a considerable distance from the original seat of inflammation, be strictly regarded as of an inflammatory nature. May not the obliterating growths found to exist simultaneously in terminal arteries in widely-removed portions of the body of the same individual also be regarded not as of inflammatory nature, but rather as a secondary and formative process, closely connected with disturbances in the mechanism of nutrition, designed to adapt the vessels to a diminished blood supply?

Dr. S. W. Gross said, in view of the fact that Dr. Warren's teaching seemed so directly opposed to that of other observers, he would like to have some points cleared up. He would, therefore, ask if Dr. Warren held, 1st, that instead of the external coat where it is included in the ligature sloughing, and coming away with the ligature, the pressure of the ligature sets up an irritation which causes the adventitia to return to its embryonic state with a reconversion, after the ligature has cut through this, to connective tistue; and, 2d, whether the repair of arteries was brought about by the ingrowth of the cicatricial tissue, which he likened to provisional callus, together with some proliferation of the muscular cells of the media.

Dr. Randall said, that as the result of careful study of the subject, he had always found the clot present at at first, and that it was honey-combed even in the first few days by the contraction of its fibrin; through the spaces thus formed the blood seemed to be circulating. Cells, either original white cells or of endothelial origin, occupied the walls of these cavernous spaces, and seemed to sheathe them. The red cells early melted down into a homogeneous mass, furnishing the framework upon which the reparative tissue was built. The "plastic clot" of some observers he had not seen—the new cells being distributed throughout the old clot, as well as upon the vessel walls, and not specially collected in the immediate neighborhood of the ligature. The obliteration of the vessel was accomplished by the growth and contraction of the trabeculæ of new tissue built upon the remains of the original blood-clot. Even close to the ligature he had not found the vessel walls greatly altered, merely showing a great increase in the nuclei and in the number and size of the vasa vasorum, the lamina elastica being distinct and as a rule intact. Toward the end of the first month the new tissue was largely spindle cells, but careful staining had given no suggestion of muscular tissue. But, not having carried his study beyond the first month, he had no data upon this subject, since the development of muscular tissue is claimed to occur only at a later stage.

Dr. Formad was inclined to favor the views of Dr. Randall. The observation of Dr. Warren that the new-formed connective tissue played the most important part, was to him entirely novel. He thought probably that pressure upon the artery from without, with consequent diminution in its lumen, might bring about a condition more analogous to the growth of fœtal life than to inflammation.

Dr. Mears remarked, we are liable to be confused in considering this subject by the presence of the blood in the vessel. So far as the process of healing after ligature is concerned, we may consider only the structures which enter into the formation of the vessel wall, which is complex in character, and com-

posed of connective, elastic, and endothelial tissues. Dr. Warren has given us a very clear demonstration of cicatrization as it occurs in these structures after application of the ligature.

Dr. Tyson said the newest feature to him in Dr. Warren's observations was the part played by the muscular tissue. This apparent increase in the muscular tissue he was inclined to believe was really only a proliferation of intermuscular connective tissue. He was becoming more and more convinced that there was only one kind of inflammation—the interstitial. He feared that he might himself mistake a proliferating connective tissue with spindle cells for muscular tissue. It is true that new-formed capillaries and arterioles have muscular walls, but the development of these seemed to him to be a slower process. He had expected to find a process of repair in the ductus arteriosus different from that in an ordinary artery. This process, he had expected, would be a true endocarditis, for it seems that the conditions of closure here are rather different from those in the ligaturing of an ordinary artery, and in the umbilical artery, where we have also ligation practiced.

Dr. Warren, in closing, said, in cases where there is much breaking down and little repair there might be a sloughing of the external coat, yet in his experiments this part of the arterial wall did not slough, but was simply absorbed by the granulation tissue, as is the ligature itself in some cases. In the normal condition, even the elastic lamina is not a perfectly continuous plate; he did not refer to these breaks, however, but to numbers of little ruptures incident to the pulling out of the wound of an artery in the act of ligature; however, this need not necessarily occur. He had not attempted to identify anything like muscular tissue early; this could not be recognized till we had a permanent cicatrix formed. He had carefully eliminated all sources of error, and it seemed to him that in almost all cases there was a considerable number of these muscular cells. The layer was not always as well marked as in his diagrams; especially was this true of human cases, but these had all been in alcohol for some years; of the fresh specimens, he had selected only those in which he had considered the process complete. In a specimen which he had here to-night, through an opening in the lamina elastica cells could be traced from the muscular layer, those in the inside resembling exactly those outside. These facts, together with the fact that we have normally a few muscular cells inside of the lamina elastica, lead him to believe in the proliferation of the muscular tissue. The disintegration of the blood-clot is accomplished by granulations growing inward from the callus, there being two sets of blood-vessels, one in the granulations, the other (blood-spaces rather) in the clot itself; these unite about the end of the first or second month.

W. E. Hughes, M. D., *Recorder.*

NEW YORK PATHOLOGICAL SOCIETY.

Regular meeting, December 9, 1885.

John A. Wyeth, M. D., president, in the chair.

Perinephritic Cysts.

Dr. T. M. Pruden reported the result of the microscopical examination of the cystic kidneys presented by Dr. Boldt for a candidate at the last meeting. The perinephritic cyst on the right side contained a litre of gelatinous fluid, while that on the left side contained three hundred cubic centimetres. The surface of the kidneys not covered by the sac of the large cysts was smooth, and on this side was considerable interstitial nephritis. On the other side were a number of small cysts containing a fluid similar to that in the larger sac. The uriniferous tubules also had become distended with a similar fluid, being converted in places into small cysts. This process was probably due to insinuation of the fluid from the larger cysts into the tubules. The specimens were interesting and rare.

Dr. Pruden then presented for a candidate a specimen of carcinoma of the stomach, liver, and omentum.

Sarcoma of the Liver.

Dr. H. J. Boldt presented a part of a sarcomatous liver which weighed nineteen pounds and a half. It had been removed from the body of a woman, and was chiefly interesting from a diagnosoic point of view, some physicians having supposed the enlargement to be due to amyloid change, probably of syphilitic origin. Dr. Boldt made a later diagnosis of malignant disease.

Cystic Degeneration of the Kidneys and Liver.

Dr. J. West Roosevelt presented the specimens which were removed from the body of a man who died in the Roosevelt Hospital, July 12, 1883, having been admitted on the 6th of July. He had suffered from symptoms which could be attributed to renal

trouble for some time before; when he entered the hospital there was some dyspnœa, which increased, and death took place from œdema of the lungs. The urine contained a small amount of albumen, no casts, was of low specific gravity. The liver and abdominal veins were enlarged.

The lesions of chief interest were found to be in the liver and kidneys; the liver contained numerous cysts, varying in size from a lemon down; the kidneys were converted into cysts, which retained something of the shape of the original organs. The speaker said he had, in a brief search, found only four similar cases recorded in medical literature.

Pyonephrosis.

Dr. Roosevelt also presented the kidneys and bladder in the case of a man who entered the hospital with the symptoms of the last stage of pyonephrosis. A stone was detected in the bladder. The autopsy showed one kidney much enlarged, the so-called surgical kidney; the other had been reduced to a small cyst. The walls of the bladder were greatly thickened; the viscus contained a stone the size of a walnut.

Necrosis of the Fibula.

Dr. Wackerhagen presented about two and a half inches of the lower end of the fibula, removed for necrosis, in the case of a girl thirteen years of age, who, about two and a half years before, had sustained an injury of the ankle, followed some months later by spontaneous rupture of an abscess. The lower end of the fibula was removed about seven months ago; the surface of the astragalus was slightly involved, and was scraped. There was no further disease, and the patient now had a healthy joint.

The president remarked that he had never seen necrosis of the fibula without involvement of the bones of the tarsus. He thought it was a rare affection.

Infarctions of the Kidneys; Ante-mortem Heart Clots, etc.

Dr. L. E. Holt presented the heart and kidneys removed from the body of a child about seventeen months old, which had died with symptoms of marked cerebral irritation, depending upon teething. There was marked cyanosis a short time before death. At the autopsy there was found slight milkiness of the pia mater. The vessels of the right hemisphere were extremely engorged, while the left hemisphere was seemingly anæmic. The sinuses on the left side contained firm decolorized clots, while those on the right side were free. The arteries were examined as far as the second bifurcation, and no obstruction was found. Both sides of the heart contained large, firm, closely-adherent clots, which occurred, as Dr. Holt believed, ante-mortem. The kidneys showed white infarctions in a marked degree.

Multiple Myoma of the Stomach and Bladder.

Dr. R. Van Santvoord presented specimens removed from the body of a man seventy years of age, who entered the hospital about two days before death. He was suffering chiefly from dyspnœa. There was considerable fluid in both pleural cavities, and a loud systolic murmur of uncertain origin. He died apparently from dyspnœa. The autopsy showed pleurisy and fibroid phthisis. The lesions of chief interest, pathologically, were in the stomach, rectum, and bladder. The stomach was eight inches long, and a saddle-shaped neoplasm, two and a half inches in length and breadth, and about half an inch thick, occupied the lesser curvature; it was apparently situated in the muscular layer, and was composed of muscular tissue. The capsules of the liver and spleen, and the mesenteries, were thickened, and adhesions had formed among the abdominal organs. The liver and spleen were considerably diminished in size. The vessels of the kidneys were in an advanced stage of fibroid degeneration. The bladder contained a circular tumor, one inch in diameter, one-fourth of an inch thick, presenting the appearance of a muscular growth. There was also a similar tumor in the wall of the rectum, which was adherent to the base of the bladder by an old process. The aorta was markedly calcareous; the cerebral vessels were very brittle.

The Physical Signs of Pneumonic Consolidation of the Anterior Edge of the Upper Lobe.

Dr. Van Santvoord also presented specimens removed in the case of a man who said, on entering Randall's Island Hospital, that he had been sick seventeen or eighteen days with cough and some fever, but no expectoration. Dr. E. D. Maxwell found marked dullness over the upper lobe of the lung, flatness over the lower lobe, absence of respiratory murmur over the lower lobe, and marked amphoric breathing above. The following day amphoric breathing had disappeared over the upper lobe, bronchial breathing having taken its place; flatness had disappeared over the lower lobe, and there was bronchial breathing where there had before been absence of respiratory murmur. The urine contained albumen to the extent of

about one-eighth of its bulk, epithelial and blood casts, and free blood. The last day of his life the patient had three epileptiform convulsions, and died in a state of coma. At the autopsy the arachnoid was found thickened by a chronic process, the pia was infiltrated by a somewhat gelatinous-appearing lymph, which was infiltrated with pus, covered the whole of the brain, and extended into the spinal cord. There was gray hepatization of the right upper lobe, of particularly firm character, and differing from that ordinarily seen in the upper lobe, in that it approached very nearly the anterior edge of the lung. This point was interesting in connection with the physical signs. Dr. Janeway had called attention to the fact that in pneumonias of the upper lobe, in which the infiltration extended almost or quite into the anterior edge, there was frequently not only amphoric respiration instead of bronchial, but also cracked-pot percussion note; the explanation being that the firm wedge of lung lying over the bronchus transmitted cracked-pot sound from the bronchus. The left ventricle was hypertrophied, and in this case the radial arteries were markedly atheromatous, while the other vessels were only slightly so. The kidneys contained a few cysts. The gross appearance was that of chronic diffuse nephritis. The condition of the urine before death indicated an acute nephritis.

The President presented specimens of

Congenital Tumors in Front of the Antetragus.

The father had the same kind of tumors, also his sister, and the growths were evidently hereditary. The specimens were referred to the Committee on Microscopy.

Tubercular Testis.

The President also presented a specimen accompanied with the following history:

David D., 55 years of age, married, a native of Holland, a cutter by occupation, was admitted to Mt. Sinai Hospital December 7, 1885. He had had a hernia on the left side for twenty-five years. About seven months ago his left testicle became enlarged and was slightly painful. The swelling increased gradually, and was treated, but did not improve. About six weeks ago the swelling began to extend upwards into the inguinal canal, and became harder and more tender. The patient has always been more or less constipated. He has had slight abdominal pains, and almost continous pain just below Poupart's ligament. He had a chill yesterday. He had a perineal abscess two years ago, due to a piece of wood he had swallowed with bread, and which appeared in the abscess. His previous health had been good. He had been treated lately for posterior spinal sclerosis. His family history was negative.

On examination, the tumor was as large as a man's fist, and evidently contained fluid. The diagnosis was, possibly, hydrocele, or simple periorchitis. The symptoms of strangulation were not clear, and it was thought best to cut down upon the mass with reference to the condition of the testicle, to the possible existence of hernia, and with a view to removing the fluid. The incision was made, and Dr. Wyeth found a double cyst. The first was outside the cord, and discharged from one to two ounces of fluid; and inside of that was a second cyst, which discharged four ounces of serous fluid. There was no hernia. On examining the testicle, it was found to be very much enlarged and nodular—the epididymis as well as the body of the organ. The testicle was removed.

The surgical point of interest was that it could not be determined whether the tumor was a hernia, or an enlarged testicle, or a hydrocele. The specimen was referred to the Committee on Microscopy.

Peculiar Cases of Intermittent Fever.

In the *Genio Medico-Quirurgico*, Dr. Palop records two cases of intermittent fever, in which he was able to discover and remove the cause, producing instant cure. One case was that of a young man who suffered from a peculiar fever, which ran through a regular cycle of modifications every week. On Sunday he would be seized with a cold stage lasting an hour, followed by a severe hot stage, with copious sweating and pain on the left side of the head. On Monday he had no fever, but the pain remained unchanged until the Tuesday or Wednesday, when it increased and spread over the whole head, without any improvement taking place until Saturday. Drugs proved of no use, and no relief was obtained until a small fluid tumor behind the left ear was discovered. On being cut into, a small quantity of blood and pus was evacuated, and a dermoid cyst found; this was removed, and the patient was relieved of all his febrile symptoms. The second case was that of a laborer, attacked with fever of a tertian type. Quinine proved useless, and the symptoms continued until an inflamed bursa over the patella was aspirated; as soon as the pus was removed, fever subsided.

Professor Verneuil on Surgical Ethics.

In his address before the French Association pour l'Avancement des Sciences, at Grenoble, Professor Verneuil gave his audience some excellent hints on the ethics of surgical practiee. "When the inefficacy of pharmaceutical and hygienic measures has been proved," said he, "and a necessity arises for operative procedures, choose always —and this is an inviolable rule—the least dangerous operation, *actum minoris periculi*, and do not be swayed in your choice by the natural reluctance of the patient, or the interested entreaties of either relatives or heirs, nor, above all, by any thought of the great trouble you may incur with but small recompense in the way of fees. Understand, too, that the least dangerons operation may in some instances be the boldest, the most radical, and apparently the most destructive. There are some maladies of the limbs in which amputation is ten times more conservative than resection, and a hundred times safer to life than expectant treatment, however attentive. In some cases of stone in the bladder, lithotrity is much more dangerous than cutting. Ovariotomy also is infinitely more benign than repeated injections of iodine. . . . . When a decision has to be made between two or more rival operations, a simple criterion is to put in the first place efficacy, in the second harmlessness, and in the third facility. There is also a second criterion still more valuable, and so simple that it can be applied in a few minutes, without any lengthened experience in practice or extensive learning, and without being acquainted with the procedures in favor at the moment in Vienna, London, or Berlin. I mean the gospel principle of doing to another what one would have done to one's self or one's own. Numbers of parents to whom I have urged the necessity of some operation on their child have, after exhausting a large stock of arguments, finally put to me the question, "What would you do, doctor, if it were your own child?" This question has never caused me the least embarrassment, for during the last thirty years I have been in the habit of putting it to myself throughout my practice in the town, in the hospital, with poor as well as with rich patients—every time, in fact, when I have had to decide on the performance or otherwise of operative measures. . . . . Of 100 possible operations, twenty are imperatively necessary, twenty are positively inadmissible, and the remaining sixty may be performed or not, according to circumstances; and surgeons may and do err in each of these classes of cases. . . . . It is in surgery as in other branches of our activity. Everywhere competition is active and severe, showing no mercy, every one wishing for the first place. From the time of Guy de Chauliac to the end of the last century, France incontestably led the way. England, Italy, and Germany entered the lists later, but are now disputing with her for the first place. Some writers on both this and the opposite side of the Atlantic affirm that we have fallen behind, doubtless because we show ourselves more solicitous about the lives of our neighbors, and make more difficulty about cutting other people to pieces, than they do. You will notice that it is precisely in those countries where there is the greatest indignation against our experiments on animals, that we are accused of timidity and senility in our surgery."

Camphor Intoxication.

The *Quarterly Journal of Inebriety* tells us that in a late number of the *Annales Medico-psychologiques*, a long account is given of some unusual symptoms following an overdose of camphor, which lasted months after. The close resemblance to many cases where, after the first profound intoxication, the nerve and brain disturbance continued for months, will be apparent to all our readers. The case was a young man with no heredity of nerve disease, and in apparent good health, who for a slight catarrh and insomnia, took, by mistake, 300 grains of camphor. Soon after, he seated himself at the dining-table, felt chilly, lost power of speech, was bewildered, and finally cried out that he was crazy. A physician was called and an emetic given, which brought up much of the camphor. He was taken to his room, and, excepting some chills and hallucinations of vision and sensations of trembling, he recovered and was out in two days at his work again. Three weeks later, he suffered from severe headache, and had a well-marked hysteric sensation of choking, and, when in bed, suffered from a sickening sensation of

swinging. Later, exact ideas of time were lost, everything seemed new and at the beginning. Although able to work, all events seemed new and strange. Sensation of his height became perverted. He thought he was higher than the houses, and suffered at the thought of the great disadvantages of his height. By striking himself on the head, he felt better. He went to an asylum, and was better at first, but finally fell into a mechanical state of existence. Was contented with everything, had no care for himself or any one, would talk and seemed to realize what was said, but had no interest, or continued memory of events. Two weeks later, he recovered and went about as usual. After six weeks' residence, went home, and, on greeting his family, was thrown into a trance state, in which he could not talk or act, but yet fully realized what was said and done about him. Two weeks after, from some excitement in his family, he had another trance state, and came out of it very weak and trembling. For a long time after, he was conscious of an unstable brain, which seemed balanced on a very slight point, likely any moment to turn over. Fragments of conversation went whirling through his mind, and at times his surroundings were all perverted. He would walk round and never remember what he was doing or where he was; was somnambulistic. From this time the case continued to recover. The disorders of sensation, and hallucinations of the senses, which he seemed to partially realize, pointed to central brain disturbance, that was undoubtedly the beginning of very grave lesions. This poisonous dose of camphor either kindled into activity a latent nerve defect, that was a legacy from the past, or it produced some cell changes in the great centres. This emotional instability, with disordered and changing sensations and hallucinations, presenting the most diverse and complex symptoms, are often seen in inebriates, although they have been months free from spirits. In other cases it follows a single paroxysm of intoxication, and lasts for months or years.

Acute Inflammation of the Occipito-atlantal Joints, with Pyæmia.

Mr. C. A. Ballance (*Lancet*) records a case of this disease with the following history: The patient was a boy six years of age, with a good family history. Four days before coming under observation he suddenly complained of pain in the neck, and kept his head quite stiff. The pain and stiffness had increased, and had prevented his sleeping at night. The spine was rigid, and the head and neck were only moved with the rest of the body. When the head was touched the child cried out, and slight pressure on the vertex or any attempt at rotation caused great pain. On examining the back of the neck, some fullness and marked tenderness were found to exist on either side of the median line in the region of the occipito-atlantal joints. On laying the hand upon the part, it was evident that the temperature was raised above that of the surrounding skin. The temperature at the time of the first observation was 100.5° F. The child was put to bed and his head fixed with sandbags and pillows. The temperature in the evening rose to 102.5°. The subsequent clinical record shows a very rapid downward progress. The next day the temperature varied from 102.5° to 103.5°. The boy could obtain no rest on account of the pain. On the third day the swelling, which had been noticed on either side of the neck, had become much more pronounced. Two days later, the whole neck was œdematous and greatly swollen, and the points from which the inflammatory process had spread were very hard. Into the brawny region an incision was made and carried down until the knife touched the transverse processes of the atlas. No pus was liberated, but in a few hours a great deal of serum had oozed out. The neck on the following day had resumed its normal size, but the patient was no better. On the twelfth day of the disease the elbow joint was painful, and soon fluctuation was detected. The patient died two days later of pyæmia—on the fourteenth day after the first symptoms of the disease. On post-mortem examination, the capsules of the occipito-atlantal joints were found to be distended, and, when an incision was made into them, fœtid pus escaped. The joints were completely disorganized; the synovial membrane was swollen and injected; the cartilage had for the most part disappeared; the bony surfaces entering into the joints, which had become exposed by the solution of the cartilage, were superficially carious. The occipito-atlantal joints were alone involved in the disease. Pus was found in the elbow joint.

A Case of Quintuple Labor.

In the *Meditz. Obozrenie*, Fasc. x., 1885, p. 1015, Dr. F. Poliakoff describes a rare case of quintuple labor which has lately taken place in the village Sarai, Sapojok district, Riazan Government. The patient, a peasant woman aged twenty-seven, who had been married nine years and delivered six

times (at full term, and each time a single fœtus), came to the Sapojok Zemsky Hospital in the beginning of February (about five months after her last catamenia) on account of enormous enlargement of her abdomen, which caused extreme difficulty in breathing and general weakness. On examination, the fundus of the oblong-round uterus was found at the highest level of the epigastric region; feeble fœtal cardiac sounds were heard in the right hypochondrium; there were felt some small fœtal parts on the left of the linea alba. In view of the enormous size of the womb, plural pregnancy was suspected. On February 28, in the evening, uterine contractions commenced; and on March 1, at eight o'clock a. m., labor ensued. The patient was delivered of five female fœtuses, which followed one another at the intervals of a few minutes, two of them being in pelvic, three in head presentations. Each of them was enclosed in a separate sac (unruptured amnion). The first fœtus (a monster) was dead; the remaining four were alive, but died soon after rupturing their sacs. The placenta, which was single, and weighed 585 grammes, was squeezed out after Credé's method. There were five amnia and a single chorion, common to all; the umbilical cords were attached along the margin of the placenta. Four of the fœtuses were normally developed, their individual weight being about 590 grammes, and their size varying from 29 to 31 centimètres. The fifth measured 41 centimètres in length, weighed 934 grammes, and presented considerable anomalies (elephantiasis-like swelling of the integuments of the head, microcephalia, defective numbers of fingers and toes, etc.). The umbilical cord of the monster contained only two vessels (one artery and one vein), while the cords of the remaining four fœtuses consisted of three vessels. These rare specimens have been presented by Mrs. A. M. Klausmann, the midwife in whose practice the case had occurred, to the pathological museum of the Novo-Ekaterinensky Hospital.

A New Method of Giving a Bath in Typhoid Fever.

In an article on this subject in the *Therapeutic Gazette*, Professsor H. C. Wood says:

As is well known, the great difficulty in the use of the bath in fevers is the trouble which is involved in moving the patient in and out of the bath-tub. The following simple device will in great part remedy this trouble, and also save the necessity of providing a portable bath-tub. The canvas of an ordinary bed-cot is to be made three or four inches wider than it is ordinarily arranged, and a broad board nailed at each end so as to hold the cot permanently open, and project above it several inches in the form of a head- or foot-board. This cot is then arranged alongside the bed of the patient so as to be on a level with the bed, and at the same time firm. Over it is spread an India-rubber cloth sufficiently large to cover it entirely, and to fall above and below over the head- and foot-board. The patient, wrapped in a sheet, is then slipped on to the cot; of course the canvas sags down, and when water is poured over the sheet the man lies half immersed in a pool. If the attendant is provided with two tubs, one containing water and one empty, and also with a large bathing-sponge, the water in this pool heated by the body can be removed by means of the sponge, and fresh cold water soused over the body enveloped in the sheet. In this way the water lying continually between the sheet and the body, as well as saturating the sheet, so envelops the person that the effect of a cold bath can be achieved, and I have seen very rapid reduction of obstinate high temperatures. If the bed upon which the patient lies be a very wide one, instead of a cot being used the mattress can be so arranged on one side as to sag down sufficiently to form a hollow for the pool, and in this way the bath be given.

I notice that Stephen, of St. Petersburg, affirms that the application of ice-bags over the supra-clavicular regions is sufficient to control the temperature in fever, owing to the fact that the cold is brought into close contact with much of the blood of the body by the large superficial veins of the neck. I have had no experience, however, of this method of reducing temperature, but it is worthy of a trial; especially as it seems to be safer to reduce temperature in low fever by external cold than by our at present known depressant antipyretic drugs.

Chancrous (Chancrelleux) Bubo.

In a note communicated to the Société de Chirurgie, M. Diday agrees with M. Horteloup in supporting the view of the occurrence of virulent bubo by absorption, and refers to his own case as one in point. M. Diday, many years ago, inoculated himself on the sheath of the penis with chancrous pus, the result being a chancre which subsequently became phagedænic, and was accompanied by a chancrous bubo. Neither M. Diday nor M. Horteloup denies that some virulent buboes are due to accidental inoculation of

the open surface after opening, but both authors contend that such cases are exceptional. To those who consider them the rule, M. Diday puts the following questions:

1. The treatment of buboes of all kinds by blistering being so common, why do not those blistered surfaces become inoculated?

2. If a bubo, after incision, were inoculated from without, the chancrous erosion ought to start from the point touched by the pus, whereas the chancrous characters always show themselves simultaneously throughout the whole extent of the incision.

3. When the edges of an open bubo become chancrous, this transformation of a simple wound into a specific ulcer occurs always about the fifth or sixth day. Now, if this change were due to accidental inoculation of the wound, why does it never take place after the first week?

4. Besides buboes, of which one may predict that they will become chancrous, there are also strumous buboes, of which one may say with confidence that they will not become so.

A patient with such a bubo has also a chancre (*chancrelle*). He is in a venereal hospital, exposed to all kinds of risks of accidental inoculation, yet the bubo that is strumous in its origin remains strumous to the end.

Subcutaneous Division of the Sphincter Ani.

In the *Med. Times and Gazette*, Mr. Pick recommends the plan of dividing the fibres of the sphincter ani by a subcutaneous incision, in cases of spasm of the rectum and fistula in ano. The author records the case of a man who suffered from intense pain and spasmodic contraction of the sphincter ani after each action of the bowels. No structural lesion could be detected, and it was determined to divide the sphincter subcutaneously. This was done by inserting the left forefinger into the rectum, and then introducing a tenotome through the skin about a quarter of an inch from the anal orifice; by means of the finger in the rectum, the point of the tenotome was carried up beneath the mucous membrane, until it was well above the upper edge of the sphincter muscle. The tenotome was then turned round, and the fibres of the muscle were divided until no resistance remained. After the operation, the patient's bowels were confined for 48 hours by means of opium; then a copious enema was given, producing a good evacuation without any pain. From this time, the patient was perfectly relieved of his trouble. The author also records three cases in which he has divided the fibres of the sphincter ani in this manner before operating for piles, and considers this a better plan than that of forcibly stretching the sphincter with the hand.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Frank L. James, Ph. D., has severed his connection with the *National Druggist*, and has accepted the position of editor of the St. Louis *Medical and Surgical Journal*. His intimate acquaintance with medical journalism will undoubtedly be displayed to advantage in his new field.

——The *Journal of Cutaneous and Venereal Diseases*, published by Wm. Wood & Co., has at present as editor Dr. P. A. Morrow, in place of Dr. Piffard, who has retired from its management. Under his care, it won for itself a high reputation, which we trust will be maintained.

——In a pamphlet of 43 pages, Dr. Joseph E. Winters, of New York city, discusses the nature and treatment of diphtheria. He is opposed to mercurials, and relies on large doses (℥j–℥ij every hour or half hour) of tinct. ferri chloridi, with full nutrition.

——The Illinois State Board of Health has issued its "Conspectus of Medical Colleges in the United States and Canada." It contains a large amount of information on medical education not elsewhere accessible.

——The annual report of the Supervising Surgeon General of the Marine Hospital Service maakes a volume of 180 pages, replete with statistics, tables of epidemic visitations, descriptions of cases, etc. It indicates conclusively the prosperous condition of this branch of the service, and its great value to the country.

——The Transactions of the American Dermatological Association at its last meeting appear in pamphlet form in a brochure of 47 pages. Papers are given in abstract by Drs. Hardaway, White, Hyde, Duhring, Denslow, Heitzman, Taylor, Stellwagon, and others, with the discussions they elicited. Many interesting facts were brought out.

——A number of decisions under the laws against malpractice in the State of Illinois, have been reprinted in pamphlet form by the

Board of Health of that State. They form a valuable body of precedents for the government of the relations of the medical professsion in general.

——A German physician, Dr. August Schott, has written a little pamphlet on the treatment of chronic heart disease, which deserves general notice (*Zur Therapie der Chronischen Herzkrankheiten*, Berlin, 1885). He demonstrates by the records of a series of cases the advantage of systematic gymnastics and bathing on this obstinate and dangerous class of affections. We ourselves have long been convinced of the general truth of these doctrines, but we have not seen them elsewhere so well or so positively set forth.

——The Lancaster County Pennsylvania Medical Society has published a memorial address on the late Dr. John L. Atlee, written by Dr. J. L. Ziegler. It is a merited and appropriate tribute to one of the most distinguished physicians of Pennsylvania.

BOOK NOTICES.

A Treatise on the Diseases of Infancy and Childhood. By J. Lewis Smith, M. D., Clinical Professor of the Diseases of Children in Bellevue Hospital Medical College, New York. Octavo, 867 pages, 40 illustrations. Cloth, $4.50; leather, $5.50. Philadelphia, Lea Brothers & Co., 1886.

That this is the sixth edition of this work is evidence enough of the excellence of its preparation. In this edition so much has been added and changed in accordance with the progress of the branch to which it is devoted that the author observes "a considerable part of the book may be considered new." Some of the most important articles, as, for instance, those on scarlet fever, croup, and cerebro-spinal fever, have been entirely rewritten. No doubt the popularity of the work will continue unabated.

A Hand-Book on the Diseases of the Nervous System. By James Ross, M. D., F. R. C. P., LL. D., Senior Assistant Physician to the Manchester Royal Infirmary, etc. Octavo, 726 pages, 184 illustrations. Cloth, $4.50; leather, $5.50. Philadelphia, Lea Brothers & Co., 1885.

The author of this volume is a Manchester physician of a wide range of observation, who has given prolonged study to his specialty as a neurologist. His work is divided into two parts, the first treating of general, the second of special neurology. The former describes the anatomy, physiology, and pathology of the nervous system, and the general symptoms and treatment of its diseases. Following this, the various special diseases are enumerated and described. The author's style commends itself for its simplicity and clearness, in which it stands in advantageous comparison with the German writers on the subject. His work will undoubtedly be read with pleasure by the general profession, for whom it is prepared.

How We Treat Wounds To-day. By Robert T. Morris, M. D. Pp. 161, 12mo. G. P. Putnam's Sons, New York.

The subsidiary title of this work explains it as "A Treatise on Antiseptic Surgery which can be Understood by Beginners." The author puts in the shortest space and in terse and occasionally eccentric English, the plainest directions as to the treatment of wounds by the modified Listerian method. His instructions are clear and sound, and can be read with profit by those not acquainted with the details of this plan.

Lectures on Syphilis, Delivered at the Chicago College of Physicians and Surgeons. By G. Frank Lydston, M. D. 12mo., pp. 184. Chicago. A. M. Wood & Co.

The class lectures here reported originally appeared in a medical journal, and have been reprinted with some emendations. They present an epitome of the modern views of this disease and the general principles of its treatment. While offering nothing new, they fairly represent the topic.

Tablets of Anatomy. By Thomas Cooke, F. R. C. S., etc. Fourth Edition. 8vo., pp. 294. Longmans, Green & Co., London.

The object of these "Tablets" is to present to the student a list of the anatomical parts of each division of the body in the most conspicuous manner possible, and so arranged as best to serve the memory. The plan seems to have been judicious, if we may judge from the fact that this is the fourth edition. The printing and display are well chosen.

Transactions of the Medical Society of the State of Pennsylvania. Vol. xvii., pp. 514. Published by the Society.

This volume, equally satisfactory in its contents and manufacture, is an evidence of the activity of the Society and its constantly increasing strength from year to year. In our report of the last meeting, we gave so full notices of the more important papers, that we need not at present enlarge upon them. Several of them are accompanied with maps, and there are few among them which do not reflect credit on their authors and on the Society.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE INHALATION OF DUST.

Dr. J. Arnold, in an interesting series of observations, has endeavored to determine the effect of the inhalation of all kinds of dust particles contained in the air we breathe (*Deutsche Med. Zeit., Dec.* 21, 1885). For this purpose he employed every variety of dust, soot, emery, fine dust of sandstone, ultramarine, etc., and in the animals experimented upon he found these substances again in the trachea, the bronchial tubes, the air cells, and finally in the parenchyma itself of the lungs. These particles, therefore, penetrate through the epithelial covering and the walls of the air-cells, and from some observations of the author, it seems to be proved that these particles pass between the epithelia of the air-cells, whence they advance along the lymphatic vessels, and ultimately reach the bronchial glands.

When the inhalation of these various substances was discontinued, the dust was gradually removed from the lungs, until, if the animals lived long enough, finally not a particle of dust remained in the lungs. This favorable result was more rapidly obtained in vigorous animals than in those debilitated from any cause whatever, and this absorption progressed the slowest in those where the condition of the glandular system seemed to indicate a state similar to that observed in scrofula of the human being.

The dust is partly carried totally off, and partly deposited in the bronchial glands. The plain dust usually finds the limit of its further progress in these glands.

Arnold's experiments also prove that the dust thus carried into the parenchyma of the lungs and into the bronchial glands, never proceeds further into the system to remote organs; and the cases therefore, where the so-called dust metastases were met with in the liver, the spleen, and other internal organs, need a different explanation from that formerly given. A clear evidence of this fact we find in two well-known diseases: stone-mason's and miner's lung. The fine particles of sand-dust inhaled by a stone-mason, and gradually accumulating in the lungs in such a quantity as to cause the death of the individual under symptoms strongly resembling those of tubercular pulmonary phthisis, and the fine coal-dust, which so frequently affects the lungs of miners in coal-districts in a similar manner, are never found in any other organ. But the experiments of Weigel and Roth have proved the existence of veins in connection with the bronchial glands, and when such a gland becomes irritated from the foreign particles it contains, which

it, however, only does in persons with a tendency—inherited or acquired—to bronchial enlargement, these same particles may proceed further, reach the thoracic duct, and from there any other part of the system.

The tubercle germ is either carried directly into the lungs with the dust inhaled, or the irritation and inflammation caused by these foreign substances prepares the soil most suitable for the further development and maturity of the germ. If individuals with such dangerous occupations would simply wear a so-called respirator—a fine sieve-like net, made of gold wire (to prevent rusting), and covered with black silk, and placed over the mouth—or make use of a similar contrivance, the diseases above-mentioned might be easily prevented; but it is peculiar that mechanics all the world over are very stubborn in the adoption of any such preventives. How many coal-miners still neglect to carry a safety-lamp or are negligent in its use, and how few impregnate their clothing with some fire-proof mixture to escape the dreadful dangers from the burning of exploded gas!

All that physicians and representative medical journals can do is to draw the attention again and again to methods by the employment of which dangers to health and life might be avoided; but if those most interested in their use continue stubbornly to refuse these protections, it becomes the duty of the law-makers to force such men to do what is intended for their benefit alone.

THALLIN, ANTIPYRIN, AND KAIRIN.

The Medical and Surgical Reporter has kept its readers well informed of the investigations which have been made during the last year, especially in France and Germany, concerning the effect of the three new anti-febrile remedies—thallin, antipyrin, and kairin. There is no doubt that all of them decidedly influence the high temperature occurring in febrile diseases, but the point has not yet been determined in what cases the first antipyretic, and in what other diseases the second or third, is indicated.

A debate was, therefore, of great interest, which took place November 3, in the Paris Academy of Medicine, as it referred to the action of the three drugs mentioned. In a previous meeting, Dr. Jaccoud had pronounced the opinion that thallin was by far preferable to antipyrin, but that both possessed no therapeutical value, and should be discarded.

Dujardin-Beaumetz took up the subject, and maintained that just the opposite was true. Antipyrin does not cause any disagreeable effects, while thallin acts upon the vascular system, and diminishes the temperature by decreasing the respiratory power of the blood. Thallin can, therefore, not be employed in infectious diseases, where the blood already is altered. The same may be said with regard to kairin.

Antipyrin greatly differs from both. It has no influence whatever upon the malady itself, and one may use it, for instance, in typhoid fever, so as to reduce the temperature to the normal without diminishing in the least the gravity of the disease or its duration. Some patients cannot take antipyrin, as it causes in them profuse perspiration, which greatly lessens the strength of the sufferer. But this admitted, Dujardin-B. praises its usefulness in tubercular consumption, where he has derived great benefit from its administration, and also in septic fevers, where it is more to be relied upon than either quinine or salicylic acid.

In tubercular phthisis life is shortened and the general malaise of the patient increased by a high temperature; and as the latter can be completely controlled by antipyrin, this remedy does not only prolong the existence of phthisical individuals, but it also greatly augments their comfort.

The debate ended by those present agreeing that of the three new antipyretics—antipyrin, kairin, and thallin—the first merits preference; that all three reduce the temperature, but that antipyrin has the least disagreeable effects, and that none of the three drugs is able to change the character or the course of the disease, or to influence the prognosis in the least.

THE PREPARATION FOR SANITARY LEGISLATION.

A society has been formed in France for the extirpation of dogs which are allowed to run loose without muzzles. The method is simple. Each active member is provided with small balls of meat, in the middle of which is placed a lethal dose of strychnine or other rapid poison. The ball is tossed in tempting nearness to any unmuzzled cur which may be met, he gobbles it down, and in a few minutes the community is rid of this possible source of rabies. The society addresses itself to a laudable end, and it would be a benefit to humanity if it would extend its branches well over the world.

But apart from this, the fact quoted indicates in what manner it is desirable for the

community to be prepared for the reception of sanitary laws. Here more than elsewhere the general rule advocated by Auguste Comte comes into play. The community should be prepared for such legislation by previous instruction, before such enactments are actually spread upon the statute books. The instructors to whom we must look to prepare the public mind are primarily the members of the medical profession. Hence arises the importance that education in the principles of hygiene and sanitation should form not merely a part of the curriculum of the student, but should be a regular subject of reading for the practicing physician.

In spite of these obvious facts, few physicians take much interest in these topics. Books on sanitary themes are notoriously dull of sale, and journals devoted to them are little supported. Let us hope that the near future will see a change in these respects.

Notes and Comments.

Disease of the Umbilicus in the New-born.

Dr. Ludwig Fürth had the opportunity to study a large number of cases of disease of the umbilicus in the new-born in the Vienna clinic. From his report in the *Wien. Klin. Wochenschr.*, 11, 12, 1885, we translate the following:

"Simple, but more successful than anything else, is the following cure of umbilical hernia, which has never been known to fail in the Vienna general clinic: Small square pieces of soft linen are put up in pyramidal shape over the hernia; in their centre a linen button (common button spun with linen, as generally met with in drawers for men) is so applied that the button—which must be of the exact shape of the opening — just closes the opening, and finally the whole is fastened with a suitable linen abdominal bandage. Gradually, as the opening by contraction diminishes in size, a smaller button must be selected. If this procedure is faithfully carried out, the uniform result at the Vienna clinic is a proof of its success."

Excoriation, blennorrhœa, and ulcus umbilici, demand a treatment with astringents. The best method is first lightly to touch the affected part with the solid nitrate of silver; then a salve consisting of one ounce of benzoated zinc ointment, a drachm of Peruvian balsam, and four grains of carbolic acid, is locally applied with patent lint, and when almost healed, but evincing great slowness towards the end, the part is washed twice daily with aromatic wine, and this application is then followed by the salve.

The real sarcomphalus, consisting in the formation of granulations, is thus treated: if they are large enough a ligature is applied, otherwise they are touched with nitrate of silver.

Inflammation of the umbilical artery is not rare. A development from it of erysipelas has never been observed in Vienna. Here, too, it is well occasionally to touch the inflamed part with nitrate of silver; in the interval, astringents and antiseptics should be applied.

Umbilical phlebitis is a dangerous disease. It mainly attacks debilitated infants, and is apt to give rise to erysipelas and phlegmonous abscesses, though we believe that the phlebitis itself is already caused by the infectious material causing the last-named maladies. Our art is here powerless; when once developed, it generally ends fatally. We can only try to prevent infection by strict antisepsis.

Concerning bleeding from the umbilicus, it is rare, and generally happens between the fifth and tenth day. It is often accompanied by icterus, and if real hemorrhage, admits invariably only a doubtful diagnosis. The only good result W. has seen was from a ligature en masse.

Prophylaxis and Treatment of Thrush and of Intertrigo in Nursing Infants.

The Obstetrical Clinic in Leipzig has published for years special reports concerning the results of observations made on infants. Dr. Aug. Wolff has recently recorded the experience gained at the clinic in thrush and intertrigo of nurslings (*Arch. f. Gynæk.*, Bd. 24, Heft. 3, 1885).

It is well known that infants prematurely born and such otherwise debilitated, especially suffer from the diseases mentioned, if the cleanliness doubly necessary in such infants is not scrupulously carried out. Occasionally, but not often, both maladies attack the same infant. While the development of thrush is undoubtedly connected with the mode and manner of nutrition, the latter has scarcely any influence on intertrigo, except that nurslings suffering from intertrigo do not grow so well, and are specially liable to intestinal catarrhs. Thrush may become dangerous in consequence of its interference with the nursing of infants, while intertrigo, even in its gravest form, never becomes a fatal complaint.

To avoid the breaking out of aphthæ or

thrush, the buccal cavity of children is cleaned several times a day by the aid of a soft linen rag dipped into pure cold water; milder cases of the disease are treated in the same manner, while in graver forms the affected spots of the cavity are brushed over with a camel's-hair brush, saturated with a solution containing five parts of borax to twenty-five parts of pure honey. It has generally been supposed that honey favored the development of the spores giving rise to aphthæ, but the experience at the Leipsic clinic seems to have proved the contrary, while it greatly assists the treatment, the most irritable infants not objecting to the application after it has once been made; while the addition of glycerin, though also bestowing upon the solution a sweetish taste, has the drawback of causing a heating sensation, generally very disagreeable to the young sufferers.

Intertrigo is also prevented by frequent ablution with cold water; if the disease shows itself in a higher degree, the parts are covered with cotton wadding, which has been deprived of its fat (absorbing cotton). No medicine whatever, either externally or internally, is administered, but the results have been uniformly favorable, and such as to compare well with those obtained in other institutions.

Ammonia in Anthrax and Carbuncle.

Dr. Leonidas Averdano, in a paper read before the Union Fernandina, a Lima medical society, testified to the great value of ammonia in anthrax and "carbunculous diseases." Indeed, he expressed his opinion that it "is a specific, and that it should be the only drug used." In cases of malignant pustule, he advises that after an incision has been made, some drops of the officinal solution of ammonia should be introduced into the wound, with the hope of destroying the bacilli there and of the ammonia finding its way into the circulation before the bacillus does and thus converting the blood into a fluid in which the parasite cannot multiply. In addition, some ammoniacal salt, such as the acetate, should be given internally, and on the slightest suspicion of general infection resort should at once be had to intravenous injections of ammonia, in doses of ten drops of the official solution diluted with an equal quantity of distilled water. In cases of malignant œdema and carbunculous fever, too, "the microbe should be attacked directly in the blood, ammonia being injected into the circulation." The author detailed several cases in which immediate improvement and ultimate recovery had taken place in patients apparently moribund, by the use of repeated ammoniacal intravenous injections. He concluded by claiming for Peruvian medicine the honor of having suggested and proved the value of intravenous medication in no less than four different diseases: Dr. Leno Alarco having first injected chloral in tetanus, and ammonia in septicæmia or purulent infection; Drs. Armando Vélez and F. P. del Barco having employed capsicum injections into the veins of yellow fever patients; and Dr. Néstor Corpancho and himself having originated the treatment above described in carbuncle.

Diphtheria Cured by Tolu Varnish.

Dr. Richard Lord thus writes in the *Brit. Med. Jour.*, December 12:

"M. O. L., aged 13, complained, at 2 o'clock on November 10, of malaise. She was in bad spirits, owing to the death of one of her schoolfellows from diphtheria. A saline aperient was ordered, and taken in the evening. Next morning, at 7 o'clock, she said she felt 'all right,' but complained of sore throat.

"On examination, a thick, well-formed, greyish-looking patch, rather smaller than a florin, but of oval shape, with gangrenous edges, was seen over the right tonsil, and on the right posterior pillar of the fauces. At 5 o'clock in the afternoon, the patch had somewhat increased, and two small patches were seen on the other side. The diphtheritic spots were covered with tolu varnish, as recommended in Dr. Morell Mackenzie's work. Tincture of perchloride of iron, with glycerine and chlorate of potash, was prescribed as a constitutional remedy. The patient expressed herself greatly relieved by the varnish, and I applied it twice a day, instead of once, as advised by Dr. Mackenzie. In about forty-eight hours from the time when it was first seen, the membrane began to disappear, and, on the evening of the fourth day not a trace of it remained.

"I may add that it is important that the fauces and tonsils should be first well dried with blotting-paper. The solution can be most conveniently applied with a camel's hair pencil fixed into a long wooden penholder, as supplied by Messrs. Maw. The method of treatment which I have found so successful in this case being, I believe, little known, I think I shall be doing a service to my brother practitioners in placing it on record."

A New Disease.

The *Medical Record*, December 26, tells us that Dr. Lutz has observed in the province of San Pablo, Brazil, several cases of a peculiar disease, of which he has never seen a description. It begins with vomiting and diarrhœa, hoarseness and a cough, and frequently coryza and catarrhal conjunctivitis. Then appears œdema of the skin, accompanied sometimes by ascites and a peculiar dermatitis, under the form of an erythema; invading first the lower parts, and then spreading over the whole body in patches of variable extent. This erythema does not disappear under pressure of the finger, and becomes gradually of a dark purple color, and finally black. Desquamation takes place in large strips, leaving a tender epidermis, which, in the negro, is without color. There is fever at the commencement of the disease, and grave anæmia occurs as a sequela. The duration is several months. It begins generally with symptoms of gastro-enteritis, or of bronchitis, and œdema and ascites appear only after several weeks. Of 23 cases seen by Dr. Lutz, 10 died, 6 recovered, and the result in the others was unknown. The disease affects chiefly infants who have been weaned, and is probably due to some special food. The author states that it bears considerable resemblance to pellagra.

Salt Water Baths in Enteric Fever.

A Russian physician has made a number of observations on the effects of baths consisting of solutions of common salt of various degrees of concentration on the temperature of patients with enteric fever, as compared with those produced by fresh water baths. He finds that in every respect the saline baths are the more effectual, but that 4 per cent. solutions are not materially superior to 2 per cent. or 2½ per cent. solutions. The maximum reductions of temperature with salt baths were, at intervals of half an hour, one hour, two hours, and three hours, 1.9°, 1.4°, 1.4°, 1.1°C. respectively, and after fresh water baths of the same temperature and duration, 1.5°, 1.2°, 1.2°, 0.6° C. The minimum reductions in the case of the saline baths were similarly 0.8°, 0.4°, 0.2°, 0.1° C., and in the case of the fresh water baths 0.6°, 0.3°, 0.1°, 0.1° C. The pulse, too, is further reduced by saline than by fresh water, the maximum reductions obtained being 34 with salt and 26 with fresh water, and the minimum reductions 14 and 10 respectively. There was also a difference in the respirations, amounting to from 2 to 6 per minute, and it was noted that they became deeper and more regular after the saline than after the fresh water baths.

The Barometer as a Guide to Health.

Dr. Veeder (*New York Medical Record*, November 7,) observes that the fact is familiar that many persons liable to rheumatism, headache, and similar ailments, are liable to reproduction or aggravation of their pains when barometrical changes take place, and are enabled by means of these pains to foretell changes in the weather. This he attributes to difficulty in the adjustment of the volume and rate of the circulating blood to the varying atmospheric pressure on the surface of the body. Ordinarily the results are not serious; but Dr. Veeder believes that there are cases in which barometrical movements are of prognostic value. He has noted several deaths from apoplexy at times when there were excessive fluctuations of atmospheric pressure, and he believes that at such times over-excitement, over-eating, improper clothing, and the like, may induce most disastrous consequences in those who are predisposed to apoplexy, the weakened blood-vessels being already subjected to unusual strain by unfavorable atmospheric conditions. He recommends, therefore, that those who are advanced in years, or are subject to indications of an apoplectic tendency, should be warned to exercise great moderation in all things whenever mercury is seen to be unusually active in its movements.

Dislocation of the Ungual Phalanx of the Thumb.

Dr. R. B. Jessup, Jr., of Vincennes, Ind., reports the following rare case to the *Med. Record:*

"Mr. Hoké, a Frenchman, sixty-five years of age, residing three miles south of town, fell into his cellar November 9, 1885, sustaining various bruises of the body and head. He was well enough on the third day to come to town to have his thumb examined. In his fall he injured it, and as seen by me, there was considerable swelling, and the second (ungual) phalanx was immovably fixed in a position almost at a right angle to the line of the first phalanx. Careful examination revealed the articular surface of the second phalanx looking backward, and the phalanx displaced in the same direction. The reduction was simple. Flexion was forcibly made, and at the same time pressure in a forward direction was exerted on the articular surface of the phalanx. This was

seen by another surgeon, and was undoubtedly a case of simple dislocation of the second (ungual) phalanx backward on the first phalanx."

Determination of the Sex of the Fœtus.

The possibility of determining or rather of making a good guess at the sex of a fœtus before birth has occupied the attention of a good many observers at various times. One of the latest contributions to the elucidation of this question is supplied by a paper by Señor Juan B. Bidart, who examined 100 cases—ninety-nine in the maternity ward of the San Francisco de Borgia Hospital in Santiago, Chili, and one at home—his own wife, in fact. His observations were mainly directed to rapidity of the beats of the fœtal heart at the termination of pregnancy; and the conclusion he arrived at was that when the number of beats is below 135 a minute the child is usually a boy, and when the number is above 145 it is generally a girl. He found that under these circumstances he could diagnose the sex correctly in 92 per cent. of the cases. When, however, the beats were between 135 and 145, it was quite impossible to do more than guess at the sex. Frequent examinations must be made before the rupture of the membranes, so as to obviate the chance of mistaking a temporary irregularity for the ordinary rhythm. Of course, the auscultation must be made in the intervals between the pains, if labor has already commenced.

Dr. Parvin tells us that a friend of his in Louisville holds the same opinion, and is very often correct, but he (Dr. P.) does not place any reliance in this sign.

Death from Round Worms.

The *Deutsche Medicinische Zeitung* gives an account of a unique case of what was supposed to be an infectious disease which appeared simultaneously in two brothers, the symptoms being of a gastro-intestinal character. One of them, aged seven, at last died. On examination, a reddened, inflamed-looking coil of intestine attracted attention, lying superficially in the right inguinal region. It appeared to be tense and distended by something, and when opened was found to contain a huge quantity of ascarides lumbricoides, all matted and entwined together, completely blocking up the lumen of the gut. No peritonitis existed, and the rest of the intestine was healthy enough. After this, of course, there was no difficulty in devising a treatment for the survivor, who under a brisk vermifuge passed some twenty worms, and before long was convalescent.

Method of Administration of Hypnone.

The *Med. News* tells us that Vigier, to whom Dujardin-Beaumetz presented a large quantity of hypnone for experiment, makes the following report:

Hypnone is very sparingly soluble in water, and but slightly soluble in glycerine. Its solubility in alcohol permits the establishment of the following formula:

℞.	Hypnone,	gtt. j.
	Alcohol fortior,	gtt. xvj.
	Syrup of wildcherry,	gtt. xvj.
	Syrup of orange-flowers,	f. ʒj.

Add the hypnone to the alcohol, then add the syrups, mix, and preserve in a stoppered bottle.

The amount of hypnone necessary to induce sleep varies from four to ten drops, taken at one dose. Fractional doses are not efficient.

Facial Paralysis.

To a recent meeting of the Midland (England) Medical Society Dr. Suckling showed a man, aged twenty-six, suffering from facial paralysis with inequality of soft palate and deflection of the uvula. Two years ago he was thrown out of a trap on to his head. Purulent discharge followed from both ears some weeks later, ending in absolute deafness and facial paralysis on the right side. The faradaic and galvanic irritability were quite lost, the uvula was deflected to the right, and the posterior pillar of the fauces on the left side was much narrower than on the right. Dr. Suckling considered the palatal changes to be interesting, since Dr. Gowers says he has never seen the soft palate affected in facial paralysis.

Pleurisy in Pertussis.

Dr. Zabala, writing to the *Bulletin de Thérapeutique*, August 15, states that during a recent epidemic of pertussis, in which about 30 cases came to his share, he met with two cases of pleurisy in children nine and ten years of age, in which the presence of fluid was ascertained by aspiration. In one of these cases the effusion disappeared after the application of two blisters; while vesication proving of no avail in the other, he succeeded in producing abundant sweating and disappearance of the liquid by means of two hypodermic injections of a centigramme of the nitrate of pilocarpin.

A Suggestion for Transfusion.

The *Med. Age* says that a St. Louis doctor cut off the tails of two lizards, and by sewing the ends of the stumps together made Siamese twins of the reptiles. Having thus demonstrated the feasibility of the operation, he suggests its utilization as a means of transfusing blood. A vigorous animal, or, indeed, another human being, might thus be attached to a patient demanding a supply of richer blood. The idea is somewhat novel, but, perhaps, not impracticable. The object of the operation having been effected, the isthmus uniting the two bodies could be readily severed.

Santonin in Amenorrhœa.

We have been taught that this drug was useful in starting up the suppressed menstrual flow, yet Dr. Armand Routh tells us (*Lancet*, January 9) that, having tried it in twenty cases (ten grains on two consecutive nights), he must conclude that it is useless in amenorrhœa associated with chlorosis, when he has often found permanganate of potash useful. In healthy and full-blooded women, santonin sems to have some power in starting a uterine flow, and apparently without causing much pain.

Pruritus.

Some cases of pruritus of the vulva and anus are of very obscure origin. Neither local mischief, intestinal, vaginal, hepatic, renal, neurotic or other disorders, can be made to account for them. M. Brown-Séquard believes that coffee may have something to do with the production of the condition in some cases, since he has seen relief follow the removal of coffee from the dietary in two instances.

Correspondence.

Treatment of Carbuncle.

Eds. Med. and Surg. Reporter:

In the treatment of carbuncle—a subject lately discussed in your journal—I never use the knife, but make a "crucial incision" (if such it can be called) with caustic potash (a pointed pencil); usually in twenty-four hours—sometimes less—a large portion of the indurated mass will be found to have sloughed, and then, after free irrigation with a syringe charged with carbolized water, I thoroughly mop the remaining portions through the opening with a saturated solution—almost a thin paste of permanganate of potassa., applying it by a swab of absorbent cotton wrapped around the end of a piece of stick or whalebone—a flaxseed poultice, well covered with powdered charcoal, being applied and changed for a fresh one at night (and next morning if the visits are in the afternoon). I generally have the satisfaction next day—forty-eight hours after the first application with the potash—of finding a clean granulating surface. After another washing with the syringe of carbolized water, if any small portions of the gangrenous growth remain, another application of the permanganate—not necessarily so strong as before—followed by the charcoal poultice, will remove them in a few hours; the carbuncular growth (or destroyed tissue) is gone, and a simple ulcer is substituted which generally heals rapidly. I have followed this method in several cases, and always with most satisfactory results. Of course it is necessary, especially if the carbuncle be a large one, to treat the *patient* also; but the exhaustion of the system is much less during a period of two or three days than it is in a siege of several weeks. I do not remember that I have ever seen a like plan of treatment reported, and the method lately published in your columns seemed to me not quite as good, certainly not as rapid. Although an earnest believer in the benefit of electricity, and especially of treating morbid growths by electrolysis whenever admissible, I doubt if it would be preferable to what I have described in this instance.

L. H. Cohen, M. D.

Quincy, Ills.

Belladonna Rash.

Eds. Med. and Surgical Reporter:

In your journal for January 9, 1886, there occurs an article entitled "Peculiar Case of Puerperal Sepsis"—the peculiarity consisting of a rash which is so rarely present in septic poisoning, and which might be so much more easily accounted for by another factor in the case, viz., the use of the belladonna ointment, that I was at once struck by this feature of the case, and was also surprised that so distinguished a practitioner as Dr. Parish, of the Philadelphia Hospital, should not have mentioned at least the possibility of the rash having been due to the use of the belladonna. The relation between the use of the ointment and the appearance of the rash is so intimate that there seems no doubt in my mind that the use of the ointment was the sole cause of the rash. In the language

of the REPORTER: "On the fourth day after delivery the left breast became a little hard, and the milk disappeared. An ointment of belladonna and mercury was applied." And now mark what follows: "The next day a rash appeared on the chest." "In three days the breast yielded to treatment." "Desquamation commenced on the fourth or fifth day from the beginning of the eruption."

Now, in reviewing the above facts, it seems to me rather more than a coincidence that the rash should appear immediately after the use of the belladonna, and that it should first appear on the part to which the belladonna was applied, and that the disappearance of the rash should so closely follow the withdrawal of the drug. From the above, it seems to me that the preponderance of the evidence is in favor of the rash being due to the toxic effect of belladonna, rather than a symptom of puerperal sepsis.

A. F. BODLE, M. D.

Grand Rapids, Mich.

A Useful Syringe for Travelers.

EDS. MED. AND SURG. REPORTER:—

I desire to call attention to a very useful syringe which has been made for me by Mr. Wm. Snowden, South 11th street. It consists of a large rubber bag, holding twelve ounces or more, according to order, to which can be attached a long rubber tube, with nozzle. The bag is filled at any time (a small funnel being attached), the tube attached, and then clamped so as to make it portable. In this way it is charged, and can be used at any time to suit the convenience of travelers. When charged with peptonized milk, or gruel, or beef peptonoids, the bag can be immersed in warm water, and thus kept at any temperature till required. It has certainly many advantages over many of the bulb syringes, or the fountain syringe. When charged it is always ready for use; can be conveniently carried; the patient can use it herself; there is nothing about it to get out of order, and it is inexpensive.

FOREIGN CORRESPONDENCE.

TIENTSIN, CHINA, Sept. 7, 1885.

EDS. MED. AND SURG. REPORTER:

It might interest your readers to hear of a case of Asiatic cholera I have had.

I was asked by Rev. Mr. Corbett, on the morning of August 26 last, if I would go see his cook, who had been suddenly taken with violent cramps. I went immediately to the hovel in which he lived, and found him stretched on a kang (Chinese brick bed), apparently suffering greatly, eyes distorted, cold and clammy skin, feeble, almost imperceptible pulse, frequent vomiting, and had had six watery stools in a few moments. I thought he was probably suffering with cholera morbus, although there was no history of the ingestion of any unusual or indigestible article of diet. I prescribed morph. sulph. gr. ¼, brandy ½ ounce, and mustard poultice to the abdomen, and left, saying I would return in an hour. In a half hour, however, I was sent for, as he was much worse. I found him in a terrific convulsion, so that it took five men to keep him on the kang. I had the men rub him well with brandy while I was getting my hypodermic syringe ready, and as soon as ready I injected morph. sulph. gr. ¼ into his left arm. As soon as the convulsion wore away, I attempted to give him more brandy, but he could only take it with great difficulty, owing to the muscles of the tongue being partially paralyzed. I thought he would die every moment, for his eyes were fixed and he was entirely unconscious; but I ordered the men to keep on rubbing him with the brandy. I now "took in" the case, and appreciated its nature; after a half hour of rubbing the man began to revive somewhat, and soon muscular twitching commenced, when I gave him another granule morph. sulph. gr. ¼. I soon saw him easier, and left for a while. After I left, he had one more convulsion, after which the disease seemed to have abated, but the man was cold and exhausted. I ordered then bismuth subnit. 10 grs. every 3 hours, and brandy a teaspoonful every two hours. Difficulty of swallowing kept up for several days, and the man was unable to walk for a week, and such emaciation you could scarcely credit after a few hours' illness. When I left Chefoo he was fairly convalescent.

I find the physicians here all use Squibb's cholera mixture, and apparently with great success. It is:

℞. Chloroformi puris.
Tinct. opii.
Tinct. capsici, āā f. ℥j.
Alcohol, adde q. s. ft. f. ℥viij.

Dose, a teaspoonful in wineglass of water every half hour as long as necessary.

And all believe firmly in mustard to the abdomen.

I thought, in view of the possibility of a visitation in America, and the interest felt in the subject generally, these notes might be of interest. About ten deaths from cholera a day has been the rule all through August in Chefoo, where I was stopping, but it was confined entirely to the Chinese.

ROBERT COLTMAN, JR., M. D.

NEWS AND MISCELLANY.

Mission Hospital, Hangchow.

The Edinburgh Medical Missionary Society's quarterly paper states that the Mission Hospital in Hangchow was opened by the bishop on May 14, 200 Chinese and a number of English and American missionaries being present. The Mandarins, from the Governor downwards, subscribed liberally towards the building, and Dr. Main, who is in charge of the medical mission, is to be congratulated on having won the confidence of the highest classes of Chinese by his medical skill and devotion to his work. From a Chinese sketch which has been received, the hospital seems a beautiful and commodious building, situated in a garden, and surrounded with spacious verandahs. The foreground of the picture is filled in with a procession of old and young, halt, lame, blind, and otherwise afflicted persons, some carried on the backs of men, others in chairs and basket stretchers, others helping themselves along with the aid of crutches, and all wending their way to seek relief from the foreign physician. The hospital is a two-storied building with two wings, and a high central cupola, intended to contain a four-dial clock, which will be visible on all sides throughout the greater part of the city. There are four large wards, with twelve beds in each, besides six private wards, and two guest-rooms where foreign patients can be accommodated. There are also consulting and operating rooms, a large dispensary, students' rooms, and a lecture-room for the students, of whom already the doctor has thirteen. There is also a chapel, seated for about a hundred, in which services are held every morning and evening, while at the outer gate a reading-room for the public is open all day. One of the large wards is appropriated to opium patients, and was filled the first day it was open; and another large isolated ward is for female patients, to whom Mrs. Main devotes much time and care. There is every provision made for cleanliness and ventilation throughout the building.

The Milk Supply of Cities.

The *American Agriculturist* for January says:

The business is profitable enough to warrant the greatest care and the strictest integrity. A one hundred acre farm in Orange and other counties will sustain thirty cows, and yield two thousand five hundred dollars in milk product. It will produce most if not all of the food the herd requires. The increase is a source of profit, and the household can procure most of the agricultural products for its own use from the land not devoted to pasturage. These statements are rather below the reality, and they make less excusable the custom of forcing a milk supply, by an excessive or harmful use of deleterious food. But the milk-producers may, as a rule, be credited with carefulness and cleanliness in the preparation of milk for the market. Cans are bright and sweet, and cold spring water or ice is freely used to keep the milk cool and marketable, and to give the city customer a safe and healthful beverage. In no product does the country come so close to the town as in this matter of the supply of milk. The producer has the consumer at his mercy, and it is the serene trust of the latter in the honesty of the former upon which so much of the comfort of his life depends. This dependence grows with every year. In the year 1800 there were four inhabitants in cities to every one hundred of our population; in 1850 the proportion was twelve and a half to one hundred; in 1880 it was twenty-two and a half; in 1890 it will be at least one-fourth. And this immense aggregate must trust implicitly to the honesty of a small fraction of the agricultural population for the good qualities of one of the most essential articles of consumption. We see no reason to doubt that mutual confidence will be as worthily bestowed then as it is now.

Boylston Medical Prize Questions.

At the annual meeting of the committee for 1885, it was voted that a prize of two hundred dollars be awarded to Edward S. Stevens, M. D., of Harveysburg, Ohio, for a dissertation on "The Best Preliminary Education for the Study of Medicine."

The following are the questions proposed for 1886:

1. Influence of the Soil as a Factor in the Causation and Spread of Typhoid Fever.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of three hundred and fifty dollars.

2. The Relation of Hospitals to Medical Education.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

Dissertations on the above subjects must be transmitted, post-paid, to Morrill Wyman, M. D., 24 Church street, Cambridge, Massachusetts, *on or before the first Wednesday in April*, 1886.

The following are the questions proposed for 1887:

1. On the Identification of Human Blood in Suspected Stains.

2. Original Investigations on the Pathology of So-called Uræmic Symptoms.

The author of a dissertation on either of the above subjects, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

Dissertations on these subjects must be transmitted as above, on or before the first Wednesday in April, 1887.

The Pessimist Patient.

The *Popular Science News* says:

"Of all patients," says an English physician, "your pessimist makes the very worst. He is virtually dead before he is half sick. I speak from experience: a pessimist is a happy man as long as the sun shines, and all is going well with him; but when clouds arise, and illness comes, then there settles over both his body and mind a gloom that is but the foreshadowing of darkness to follow. A medical man may do his best for such an individual, but it is usually a thankless task. It is a wearisome thing trying to lift a fallen man who will not do a little towards helping himself.

"A good simile as regards the effects of pessimism and optimism on a physician's patients may be adduced from the different conduct of a beaten and demoralized, and a victorious, army. The former—so field-surgeons tell us—have no heart, their broken bones will not unite, their wounds take on no kindly action; the sick succumb, they die like rotten sheep; and even those who are well, in very fear grow weak and ailing. How different in the army triumphant! Wounds are called 'scratches;' the men can hardly be prevailed upon to go on the sick-list for them. Those who must keep still, feel less pain than they would under other circumstances; they sleep well, they eat well, and are soon well altogether. But the pessimist makes a bad soldier when at his best."

The Danger of Vaccination Shields.

We are glad to call attention to the warning that is issued by the *Lancet*. It seems that in his capacity as medical officer to the Local Government Board, Dr. Buchanan has issued a caution against the use of vaccination shields. Cases of erysipelas have have been traced to their use, and, having regard to their construction, it is by no means difficult to understand why such results have followed. That portion of the framework of the shield which rests on the arm, as also the bands for fastening the apparatus on, are covered with or consist of porous material, such as lint, etc.; and whenever any discharge takes place, this material runs almost certain risk of being soiled. Any subsequent use of the shield practically amounts to the use of a dirty surgical dressing, and it is well known how serious a danger this is, even to the most trivial of surgical cases. Protection for a vaccinated arm is rarely wanted in the case of an infant, for the arm can easily be altogether taken out of the clothing, care being taken to wrap the child up warmly in some loose shawl or other similar article, which is free from irritative dye. Having regard to these considerations, vaccinators are urged to discourage the use of so-called "vaccination shields," and to advise some other means of preventing irritation by means of clothing, where this may be necessary.

Edinburgh Students and the Academic Robe.

In some of the Scottish Universities, the students still wear an academic costume; for many years, however, the custom has not obtained in Edinburgh. Recently, however, the subject has been the matter of some keen discussion among many of the students; and the Students' Representative Council being appealed to on the subject, undertook, by means of a *plebiscite*, to ascertain the views of the student community. The results are now to hand; but, as we are only concerned with the faculty of medicine, we need only note that, of medical students, 601 voted for both cap and gown, 355 for neither, 46 for cap only, and 5 for gown only. Considering the large number who have not voted at all, and the considerable number opposed to the adoption of the costume, the question can scarcely be looked upon as decisively settled.

—When did Adam first use a walking-stick? When Eve presented him with a little Cain.

The Shortest Interval Between Confinements.

Dr. L. N. Davis, of Indiana, writes us:

"Dr. I. N. Trent reported last year to the Randolph County (Ind.) Medical Society the case of a lady, whom he had waited on twice in confinement at full term, within a period of nine and a half months. The first time she was delivered of twins, with forceps; the second, of a healthy boy without assistance. During the first labor she had convulsions, with albuminuria, the albumen continuing five months thereafter. Is this not the shortest interval between confinements on record?"

Personal.

Dr. Goodman has removed to No. 1509 Walnut street.

Items.

—Job was the first doctor—he had patience.

—Gray's Anatomy has been translated into Chinese.

—The grandest performance out—Niagara in her great cataract.

—A Bureau of Public Health, on the plan of those existing in Germany, has just been instituted in Tokio. The Director is Prof. Ogata, who has studied for several years in Munich, Leipzig, and Berlin, especially in the laboratories of Pettenkofer and Koch.

—At a recent meeting of the Medical Society, at Vienna, Dr. Kaposi showed a little girl attacked by pigmentary xeroderma, a very rare disease, which he described for the first time in 1870. It is observed in children of one year old, and at the beginning of their second year.

—A Catholic University has been established in Cordova, Spain, with all arrangements for the highest class of instruction. The medical faculty comprises the following professors: Physics, Don G. de Codes; Chemistry, Don A. Carbonelli; Physiology, Don M. Gonzales; Surgery and Ophthalmology, Don R. del Castillo; Medicine, Don R. Anchelerga; Obstetrics and Gynecology, Don E. Luna; and others.

—M. Paul Gibier, in a letter to the Académie de Médecine, acknowledging the honor of a reward conferred on him for his researches on hydrophobia, adds that when, in Berlin, he applied at the Veterinary School to have a mad dog, in order to pursue his researches, he was told there had not been a case of rabies for the last three years. Nevertheless, dogs are as numerous in the streets of Berlin as elsewhere, only they are all muzzled.

—The Eighth Chamber of the Paris Tribunal have tried M. Duchesne, dentist, for homicide by imprudence. He was found guilty of causing the death of M. Lajeune by the administration, without legal authority, of nitrous oxide gas, and was ordered to pay a fine of 600 francs, and 3,000 francs damages. The judgment took note of the fact that, although the business of the deceased had suffered by his death, his family had obtained immediate payment of a substantial sum, the amount of an insurance upon his life.

—Following the example of Mr. Joseph Zachnsdorf, who lately bound two Elzevir editions in human skin, another London binder has recently executed an order to encase a copy of Holbein's "Dance of Death" in the same material—assuredly a most appropriate covering for this work. These are the most recent instances of the use of the human skin for such a purpose; but they are far from unique, several criminals in olden days having been, after execution, despoiled of their integument in order that the bookshelves of some *connoisseur* of bindings might be enriched by the ghastly relic.

—Several cases of very small infants, born at or about full term, have recently been recorded in the *Brit. Med. Jour.* The late Dr. Grey collected no fewer than 20,000 observations of the weights of infants at birth, and the lowest he found recorded was 2 lbs. 6 ozs. The infant mentioned by Mr. Jebb Smith weighed 2 lbs. 8 ozs. There is now, in the East London Hospital for Children, Shadwell, an infant which, on the sixteenth day after birth, weighed only 2 lbs. 10 ozs.; the weight at birth was 1 lb. 10 ozs. Birth is believed to have been only slightly premature. The nails of the hands are well formed, there is an abundant crop of hair on the head, and the child takes a mixture containing barley, water, and milk (one-fifth) freely, without any intestinal disturbances.

QUERIES AND REPLIES.

MESSRS. EDITORS:

Will you kindly tell in the REPORTER notes how ethylate of sodium is used for nævus? Is it used in solution or dry?

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

1505-1556

Lecture.

TETANUS.*

BY N. SENN, M. D.,

Of Milwaukee, Wis.

Professor of the Principles and Practice of Surgery and Clinical Surgery.

Gentlemen: Having finished the subject of wound infective disease proper, I shall call your attention this evening to a more infrequent wound complication, in which the symptoms point towards the cerebro-spinal centres as the primary and principal seat of the disease. This disease constitutes one of the most terrible in the long list of surgical affections, and up to the present time is wrapped in a great deal of obscurity. I refer to tetanus. Terrible, from the great mortality attending it, and from the intense suffering with which it is accompanied; obscure, because from the present standpoint of pathology, we are still in ignorance as far as its essential nature is concerned. Tetanus, I will define as being a disease of the nervous system, due to infection of a specific character, combined in many instances with peripheral irritation of a sensitive nerve; it is characterized by spasm of definite muscular groups, and attended by a continued form of fever. If I include the adjective "infective" in tetanus, it is more on account of reasoning by analogy than positive pathological or clinical demonstration; nevertheless analogy should teach us that the well-marked period of incubation between the supposed time of infection and the development of the active symptoms resemble other forms of infective diseases very closely. That the direct cause of tetanus is due to a specific microbe, is claimed by a number of the most eminent writers, and further study and research will undoubtedly substantiate its infectious character. This disease is not a new one, inasmuch as it was well known to and described by Hippocrates, who recognized both an idiopathic and traumatic form, the latter of which he referred to wounds, abrasions, and to various pathological conditions independently of traumatism. Most all of the old classical works contain lengthy chapters on this subject, which reflect the most diverse opinions concerning its nature and etiology, which have been promulgated by different authors at various times.

In considering its geographical distribution, it has been observed that it is more frequently met with in the torrid zone, and more especially in India and South America. Statistics also show that in these countries the disease is noted for the gravity of its symptoms and its greater mortality. In speaking of race influence, it can be stated that the colored races, as a rule, are more subject to it, and when suffering from the disease, it is usually attended by a greater mortality. Age appears to exert a predisposing influence, as after exclusion of tetanus neonatorum, at least 40 per cent. have occurred in patients 10 to 30 years of age. In order to prepare you for a pathological description of this affection, I shall call your attention to a form of toxic tetanus produced by the introduction into the circulation of certain chemical poisons. There is, however, this difference between this form of tetanus and traumatic tetanus; that in the former case the active symptoms of the dis-

* Delivered at the College of Physicians and Surgeons, Chicago, Illinois. Reported by William Whitford, M. D.

ease make their appearance immediately after the poison has been brought in contact with the cerebro-spinal centres by the circulating blood. There is no period of incubation; no premonitory stage. The tetanic symptoms are well marked and fully developed as soon as the toxic effects of the drug have manifested themselves. The agents in our materia medica which are known to produce certain forms of tetanus, are strychnine, brucin, ergotine, and thebain; the forms of tetanic convulsions, however, vary according to the drug which has been administered. Taking strychnine poisoning as a type of toxic tetanus, we find that the pathological conditions are always referable to vascular changes in the brain and spinal cord—changes marked by an increased afflux of blood, by an active hyperæmia or congestion, which later result in morphological changes indicative of the first symptoms of inflammation. Experiment has established the fact that the reflex action attending toxic tetanus is the result of excessive innervation from the spinal cord. If the spinal cord in an animal is crushed at a certain point, tetanic convulsions will only take place in the muscles supplied by the nerves from the intact portion of the cord. If, again, you should divide the posterior roots of the spinal cord near their exit from the spinal canal, or the posterior columns of the cord, there will be no response to the toxic irritation in the muscles supplied by the nerves which have been divided, or below the section of the cord. Furthermore, if previous to the intoxication you should remove the brain, the pons, or even the medulla oblongata, the toxic effect of the drug will not be impaired, showing conclusively that the tetanic convulsions or spasms are the direct result from the toxic effect of the drug upon the spinal cord.

In considering tetanus as it presents itself to the physician and surgeon, we still recognize an idiopathic and traumatic form. By the term "idiopathic," I mean a tetanus unattended or preceded by an appreciable traumatism. Traumatic tetanus, on the other hand, as its name indicates, is that which follows an injury. We place great stress upon the fact that there must have been somewhere a loss of continuity of surface, *an infection atrium*, as we term it, through which the specific germs gained entrance into the circulation. In many cases of so-called idiopathic tetanus, the traumatic lesion may have been so slight as to elude detection at the time when the disease made its appearance, and yet the traumatism may have been the direct and only cause of the disease. Of the seven hundred cases collected by Thamhayn, the disease had a well-defined traumatic origin in six hundred cases, while in the remaining one hundred cases there was no apparent evidence of previous injury found, and they were consequently classified as belonging to the spontaneous variety. To impress upon you the necessity of looking carefully for the source of infection in doubtful cases, I will briefly refer to a case that recently came under my observation, where from the history of the case I thought I was dealing with a genuine case of idiopathic tetanus. The patient was a child five or six years of age, who had been ill for several days when it came under my care. The case presented all the symptoms of a mild type of tetanus, and in the absence of traumatism as a cause, I considered it as a typical case of so-called idiopathic tetanus. I had trismus, opisthotonos, and a mild form of continued fever with considerable disturbance in the function of the vascular system. After treating the case for a week or so, I accidentally one day found an exceedingly tender point in the sole of the right foot, which corresponded to a small cicatrix. On questioning more closely, the patient finally admitted having stepped upon a nail some time before, an accident which had been entirely overlooked by the parents and forgotten by the patient. Unless by accident the primary cause had been detected, this case would have been considered as belonging to the idiopathic variety, when in fact it was a well marked but mild case of traumatic tetanus. I simply make this allusion to put you on your guard in cases of so-called idiopathic tetanus, to search diligently and unceasingly for a tangible primary cause, as a slight injury or obscure cause of peripheral irritation might be easily overlooked, which would lead to an incorrect interpretation of the etiology of the disease. There may be such a thing as idiopathic tetanus, without any apparent breach of surface, as specific germs may possibly gain entrance into the circulation through an intact mucous membrane in the same manner as in other instances of wound infective diseases, the microbes finding in the cerebro-spinal centres a favorable place of localization and reproduction. Future research, however, will have to verify or contradict this supposition.

In considering the exciting causes of tetanus, I will allude first to peripheral irritation. Before the infective nature of tetanus was recognized, it was generally considered

that the disease was invariably the direct result of peripheral irritation. Clinical experience has demonstrated the important bearing of irritation of sensitive nerves, at least as a determining cause, inasmuch as in 380 cases reported by Thamhayn, it was found that 75 per cent. of them were the result of injury to the fingers, toes, hands, and feet—localities where we have an abundant supply of sensitive nerve filaments, so that it may be accepted as a well known and established fact that injuries of the hands and feet are more prone to be followed by tetanus than wounds in any other locality.

Another form of peripheral irritation, aside from the traumatic, are pathological conditions due to inflammation, which affect the sensitive nerves the same as when the irritation is produced by an injury. Tetanus produced in this manner has been observed as a complication in pleuritis, pneumonia, metritis; in fact, as a result of pathological conditions which involve in the same manner an extensive area of sensitive nerves as the effects of traumatism. In the idiopathic form of tetanus, authors still recognize a central lesion or point of irritation independently of any peripheral or eccentric pathological irritation. By this I mean central irritation by pathological conditions involving directly the brain or spinal cord, independent of traumatism. Cases have been observed in the post-mortem room where well marked pathological conditions existed in the brain and spinal cord, independent of either traumatic pathological peripheral irritation, where during life the characteristic symptoms were well marked. These cases may serve to explain the theory that the specific germs of tetanus once introduced into the system may have a special elective affinity for the nerve centres, and may there manifest their toxic influence by producing pathological conditions which induce tetanic spasms. Specific infection, then, must be recognized as the most important and essential factor in the etiology of tetanus. Recent literature on this subject seems to have established the fact, that like wound infective diseases, tetanus is simply an expression of a specific form of intoxication, which implicates, principally, the cerebro-spinal centres, the result of the introduction of specific microbes. This hypothesis does not lack analogy in diseases which are marked by a well-defined period of incubation, where a certain time elapses between the introduction of the virus and the active development of the symptoms; in other words, diseases preceded by a period of incubation, in contradistinction to diseases which are caused by the introduction of a formed chemical poison, means simply that the germs introduced at the time when the injury was inflicted keep on multiplying until a sufficient number of them have been generated in the system, when the toxic effects are announced by the active development of symptoms. If tetanus were the result of the introduction into the system of a pre-formed or chemical poison, the active stage of the disease would commence as soon as the poison had entered the circulation, which evidently has never been the case. If, however, a certain period elapses from the time of supposed infection until the active development of the disease, we recognize the fact by well demonstrated analogy that these specific germs have been introduced into the system, and have found a favorable soil for their growth and multiplication in the central nervous system until their direct toxic effects are manifested by tetanic convulsions. The period of incubation in tetanus is not as well marked and definite as in some other infectious diseases, but the same can be said of other affections where there can be no doubt concerning their microbic origin, hydrophobia, for instance. The most characteristic symptom of tetanus consists in tonic spasm of certain well-defined muscular groups, as a rule, the affection following in a descending direction. We will, for the sake of convenience, assume that tetanus has followed a compound comminuted fracture of the leg, and will describe the symptoms in their proper order. About the fifth or sixth day (the earliest period of incubation) our patient will probably complain of a certain ill-feeling in the broken limb, marked by irregular jerking; if, at the same time, he complains of general malaise, loss of appetite, of symptoms indicative of infection, we should realize that these premonitory symptoms are but the precursors of the gravest of all wound complications—tetanus. If these early symptoms are followed a little later by the appearance of trismus, there can be no further doubt as to the nature of the disease. By trismus, I mean a contraction of the muscles of mastication, as evidenced by difficulty in opening the mouth. Going still further down, other muscular groups are implicated, and we have what is known as opisthotonos, a bending backwards of the body in contradistinction to emprosthotonos, a bending of the body in the opposite direction. If the muscles on one side of the chest are affected, we have pleurosthotonos; if still further, all the muscles in the body (usually the extensors, however,) are affected, and the

entire body becomes rigid, we have orthotonos. If the muscular spasms have become well developed, involving the area of the respiratory muscles, we expect an impairment of the function of respiration. By spasmodic contraction of the muscles concerned in that function, respiration becomes imperfect on account of the constant rigidity of the muscles which are active in producing the respiratory movements.

The temperature is increased in almost every case, the rise depending upon the intensity of the infection, the acuity of the attack, and especially the rapidity with which the disease progresses. A limited area of muscular rigidity and a slight rise in temperature, are favorable prognostic indications. In some instances the temperature has been found unusually high. A temperature of 108°, even 110°, as observed by Wunderlich and Billroth, denotes great danger, and is almost without exception followed by a fatal termination. These authors have placed stress upon the importance of temperature in tetanus, watching its rise in the axilla at different times of the day, and observing that an increase of temperature beyond 104° or 105° is usually followed by death. Another curious fact has been noticed, and that is an increase in temperature after death. Wunderlich explains the high temperature in tetanus by assuming a loss of function, or a loss of control of the heat moderators in the brain, the heat centres being impaired by the direct action of the poison upon this particular portion of the cerebral mass. The post-mortal rise in temperature has been attributed by Fick and Huppert to evolution of heat during the coagulation of the myosin. The sensorium usually remains unimpaired to the last, showing distinctly that that portion of the brain concerned in that function remains unimpaired, that the disease for some unknown reason expends itself upon the motor tracts, and especially upon that portion of the cerebro-spinal system connecting the brain and spinal cord, the medulla oblongata. When the spasms are severe and prolonged, the respiration becomes impaired, the pulse small and rapid, and the surface of the body is bathed with a profuse perspiration. As the disease progresses, evidences of capillary stasis become more and more apparent, the eyes are suffused, and the visible mucous membranes livid; the tongue is coated, appetite diminished, and the bowels are obstinately constipated; all causes of peripheral irritation, as a draft of air, loud noises, etc., will provoke easily a repetition of spasmodic attacks.

The first attempt at an intelligent explanation of the morbid anatomy af tetanus was offered by Rokitansky, who found on examining the nerves supplying the injured part evidences of inflammation in the nerve itself, and hence described the disease as a form of neuritis, a *neuritis ascendens*. As proof of this view of the disease he described the pathological conditions found in the affected nerves as consisting in an exudation between the nerve fibres, granular degeneration and hyaline changes in the nerve fibres themselves, finally resulting in complete disorganization and disintegration. He regarded the disease essentially as a "neuritis ascendens," the morbid process commencing in the nerve at the point of injury, and extending by continuity to the cerebro-spinal centres. All pathologists agree that the brain and spinal cord are always found in a state of congestion, but some go still further —Lockhart, Clarke, and Dickinson, for instance, asserted that the brain was not only hyperæmic, but that there was an actual inflammation of the cortex of the brain itself, resulting in granular disintegration. Others have found, on examining the spinal cord, pathological changes well marked in that portion of the nervous system, consisting of hyperæmia, extravasation, softening, increased proliferation of connective tissue, degeneration of the anterior and posterior columns. Tyson, on the other hand, found in two cases well marked degeneration of the central canal and disintegration of the posterior columns of the cord. Aufrecht found cellular atrophy in the anterior and posterior cornua of the cord and granular degeneration of the gray substance of the cord. From all that I have stated it appears evident that so far no unanimity exists among pathologists in localizing the central lesion, but from what we have learned it becomes apparent that the most constant pathological changes are found in the upper portion of the spinal cord.

In considering the diagnosis, particular attention should be paid to the history of the case, fully eliciting the possibility of any previous traumatism or infection serving as a tangible cause. In cases of spasm of definite groups of muscles, we should ascertain the existence or absence of fever by the use of the thermometer.

Although no uniform pathological condition appears to have been found characteristic of tetanus, the weight of evidence points towards the spinal cord as the central seat of the lesion, in this respect showing a resemblance to hydrophobia, an affection which it simulates in many respects.

Muscular spasm resulting from a neurotic source and limited to a group of muscles unattended by general infection, is not marked by rise in temperature. If, on the other hand, we have muscular spasm attended by an increase of temperature (particularly if we have reason to believe that it is the result of previous traumatism or infection), the case becomes suspicious, and merits a scrutinizing examination. In tetanus, as a rule, the muscles on the extensor side are affected, while in cases of inflammatory disease in bones and joints, the contractions occur on the flexor side.

In the differential diagnosis, consider the possibility of toxic tetanus from poisoning with strychnine or any of that class of remedies which are known to produce tetanic spasms. The mental condition of the patient and the surrounding circumstances of the case will aid you greatly in eliminating such a cause. In strychnine poisoning, orthotonos is produced as soon as the drug has been absorbed, and tetanic spasms of muscular groups pass in a descending direction.

Hysteria may simulate tetanus, but you must remember that your hysterical patient cannot, for any length of time, maintain muscular spasm limited to definite muscular groups. The pupils of the eyes in tetanus are generally contracted, and the temperature is increased, while in hysteria both of these symptoms are absent.

The next disease which may be mistaken for tetanus is cerebro-spinal meningitis. If an epidemic of this disease prevails in your locality, carefully consider the differential diagnosis. In cerebro-spinal meningitis the symptoms point equally to an affection of the base of the brain, while brain symptoms proper do not belong to the clinical history of tetanus; hence, you will encounter symptoms in the former which point towards an active inflammation of the meninges of the brain, as well as of the spinal cord. If the disease has lasted for a sufficient length of time, you will look for the symptoms aside of muscular spasm which characterize cerebro-spinal meningitis. Basilar meningitis is attended by symptoms indicating irritation at the base of the brain; and as it is almost always of a tubercular nature, you will carefully inquire into the history of the case, and concomitant tubercular lesions.

COMMUNICATIONS.

LABOR COMPLICATED BY PLACENTA PRÆVIA AND AN INTRAMURAL FIBROID TUMOR.*

BY JOHN MORRIS, M. D.,

Of Baltimore, Md.

On Sunday evening, January 3, I was hurriedly summoned by Dr. William N. Hill, of this city, to a case of labor. The patient was in charge of Dr. Hill and Dr. I. I. Gross. Dr. Hill furnishes the following history of the case:

"Dr. Gross first saw the woman last March, which corresponds with the date of her first month of pregnancy. He discovered a tumor in the left side, which caused the patient to complain of pain, especially while standing. After rest for a couple of weeks, warm applications, the administration of narcotics and iodide of potassium, she became convalescent and progressed favorably during the remainder of her pregnancy. On Saturday, January 2, at 9 p. m., she was delivered by a midwife of a living child. Dr. Gross was called in at midnight, and found the woman flooding from adherent placenta. He tamponed, gave ergot, and the hemorrhage ceased. Owing to the contraction of the os and the partial projecting of the placenta, a full examination of the interior of the womb was an impossibility, although the size and appearance of the abdomen were such as to lead Dr. Gross to the belief that there was a second child present.

"At 7 a. m., Sunday, the os was closed firmly on the projecting placenta; no hemorrhage; ergot continued. I was called to assist Dr. Gross at 4 p. m., on Sunday, and found the os dilated sufficiently to admit the hand partially. Portion of placenta, not adherent, taken away. Appearance of womb as to size and irregularity remained unchanged, although examination by touch revealed no presenting part or membranes. Pains slight and at long intervals. The progress of the case afterwards, you yourself observed."

I saw the woman on Sunday evening at 6 o'clock, twenty-one hours after the delivery of the child. She was a respectable, intelligent colored woman over 40 years of age. She was quite feeble and greatly exhausted from pain, loss of sleep, and anxiety of mind, as well as the previous hemorrhage.

* Reported to the Baltimore Gynecological and Obstetrical Society.

She was, however, very patient and hopeful. Fortunately the hemorrhage had ceased. I first examined the child, as I was very doubtful, from the history given me, of the presence of a second one in the uterus. The baby was a healthy, wholesome little thing, and weighed about seven pounds. It was slightly larger than twin children usually are. I next made an examination of the abdomen. I found a tumor or hard mass nearly the size of a small child. It was solid and unyielding to the touch. It was not symmetrical in shape, and lay chiefly on the left side of the abdomen. This tumor presented no angles or projecting points, such as you would be likely to find in the case of a twin child. I then proceeded to make an examination per vaginam, and discovered the os partially closed and the placenta adherent on the left side of the cervix and anterior portion of the womb. I found great difficulty in passing the hand, and consequently determined to administer an anæsthetic. She came readily under the influence of the chloroform; I introduced my hand, broke up the attachments of the placenta, and removed it *en masse*. I then made an exploration of the uterus, and found, as I anticipated, a large tumor. It was an intramural fibroid, and filled up the posterior and left lateral wall of the uterus. It terminated in a small pedicle or tumor the size of a walnut, which, covered by the mucous membrane, projected into the uterus. The continued use of ergot had produced violent contractions, and pressed the tumor tensely upon the placenta, thus deceiving the gentlemen in attendance as to the true character of the mass felt by abdominal examination.

This case presents some very singular features. The fact that a woman over 40 years of age, suffered from a fibroid tumor, filling up the greater portion of the uterus, is in itself, I think, an unusual circumstance. The attachment of the placenta to the cervix thus occasioning a partial placenta prævia, was no doubt due to the law of selection, inasmuch as the fundus did not afford a proper nutrient matrix for the support of the child. I would here remark (en passant) that the woman had not been pregnant for twelve years. Her pregnancy in this instance was no doubt due to the accident of the ovum, which came possibly from the left ovary, finding a nidus in the healthy cervix. The case taken altogether is a profitable one, and may possibly prove of service to all engaged in it. I had not met a similar one in an experience of forty years.

TWO CASES OF DYSTOCIA.*

BY L. E. NEALE, M. D.,

Of Baltimore, Md.

Case 1. A white primipara, æt. 25 years, in labor at term with living child, presenting L. S. I. A. breech movable above superior strait and unaccompanied by inferior extremities. Descent failing, the attending accoucheur resorted to chloroform, manual extraction, Elliot's forceps, with an unsuccessful result. Another physician also tried, with the patient under chloroform, (*a*) manual extraction, (*b*) to pull down a foot. Dr. N. was called in consultation, and after many trials, including the use of Tarnier's forceps, which slipped, finally succeeded in bringing down a foot and extracting an asphyxiated child, which was restored by Shultze's method; mother well. The doctor called attention to the use of (1) Barnes' method of decomposition, (2) the obstetric forceps in such cases of difficult *frank* (Pinard) breech labors. He referred to Tarnier's explanation of the cause of difficulty in engagement and disengagement being due to the legs *splinting* the trunk, and thus preventing flexion of the same, and he thought that this fact might indicate the propriety of Barnes' plan of treatment. He cited several authorities, and agreed with those who considered this method difficult, if not dangerous, when the breech occupied the pelvic cavity, and he was of the opinion that manual extraction directly upon the breech should not be utterly ignored. Most recent authorities sanctioned the use of the forceps in *frank* breech cases, Olivier declaring that the instrument may be applied to the breech even at the pelvic brim. Lusk particularly recommended the Tarnier forceps, and Dr. N. thought the instrument should be tried before resorting to more dangerous instrumental measures.

Case 2 was one of contracted pelvis occuring in an Irish woman, 30 years of age, in labor at term with third child. Her two former labors were terminated by forceps operation, the child dying on each occasion, and in this her third labor, with child presenting vertex R. O. I. P., head movable at brim, forceps and version both repeatedly failed, and the child here also died during the accouchement. Dr. N. was then called in consultation, and with great difficulty succeeded in delivering by craniotomy a ten pound child. The puerperium was normal. The external pelvic measurements were normal; the internal conjugate was about $2\frac{3}{4}$

* Abstract of paper read before the Baltimore Gynecological and Obstetrical Society.

inches, the symphysis pubis was about 2½ inches long, and had an exaggerated inclination, and there was moreover a marked thickening of the pelvic bones. The entire build of the woman was short, stout, massive, and powerfully muscular, although there was no sign or history of rachitis. Dr. N. preferred version when practicable, to high forceps in contracted pelvis not less than 2¾ inches in smallest diameter, and he cited authority in support of this view. In such cases as labor at term with living child, he would at once resort to version if practicable; if impracticable, high forceps cautiously, and failing in this, craniotomy. With dead child presenting head at the brim, craniotomy at once. If such cases should be seen early enough, labor should be induced by Krause's method (introduction of a bougie into the uterus) about the 32d to 34th week of gestation, and even then, if *necessary*, deliver by version.

DISPLACEMENT OF THE HEART TO THE LEFT, DUE TO CONTRACTION OF THE LUNG ON THAT SIDE.*

BY H. CLINTON M'SHERRY, M. D.

Of Baltimore, Md.

The patient, whom he presented to the Society for inspection, is a man aet. 32 years, who has never been very strong, but especially during the last year has he been losing flesh and strength. He has had dyspepsia for the past fifteen months, and for six months has been greatly troubled with shortness of breath. Six months ago he was attacked with hæmoptysis, which has recurred several times since, varying in amount from a tablespoonful to a half pint of blood. He has had inflammatory rheumatism and has a most pronounced family history of heart trouble, his grandmother, aunt and sister having died suddenly from this disease. There is no family history of phthisis. Physical examination of the left side of the thorax reveals consolidation and retraction of the lung, with a cavity at the apex in front and another at about the lower angle of the scapula behind. The right lung gives evidence of very slight deposit at its apex. The left side of the chest measures at the line of the costal cartilage, 15 inches; right side measures at the same level, 16 inches, showing the left to be one inch smaller than the right. At the fourth costal cartilage the left side measures 15 inches, while the right side measures 16⅛ inches, showing a difference at this level of 1⅛ inches in the same direction. Apex beat is felt a little over two inches to the left of the left nipple, in the sixth intercostal space. In percussing from right to left the heart dullness is found to begin a little over 1½ inches to the left of a line drawn longitudinally through the centre of the sternum.

The patient has phthisis with cirrhosis of the left lung, with cavities at apex and at the angle of the scapula. No valvular lesion of the heart exists.

The point in this case to which Dr. McSherry wishes to call particular attention is the marked displacement of the heart to the left side, owing to retraction of the cirrhosed left lung, which had occurred without any history of pneumonia or pleurisy.

Displacements of the heart may be to the right or left, upward or downward, though the latter must be very unusual, for he was inclined to agree with a late author, who says "the heart hangs in the thorax like the pendulum of a clock, and when moved from side to side is raised." He said that the heart could be displaced by being pushed aside by any increase in bulk of the contents of one side of the thorax; indeed, it is one of the signs of pleurisy, pneumo-thorax, etc., but records of cases in which the heart is drawn toward the affected side are comparatively rare. Displacements to the left from such a cause he thought much more rare than to the right. He had seen one such case (reported by Dr. S. C. Chew), and had heard an interesting report of another by Dr. W. J. Jones at the last meeting of this Society.

He had also seen one case of complete transposition of all the viscera, but had never before met a case in which the heart was *drawn* to the left side by cirrhosis of the left lung, without a pre-existing history of pleurisy. He thought this displacement to the left might be mistaken for hypertrophy and dilatation of the heart.

*Abstract of paper before the Clinical Society of Maryland.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. J. M. Da Costa.

Anemia.

In some respects, gentlemen, this is a very remarkable case that I bring before you. The patient is an Italian, fifty years of age, from whom we cannot obtain a very clear history, owing to his inability to speak Eng-

lish. We can, however, glean that he has been ill for one year, during which time he has suffered from shortness of breath and pain in the chest; he has lost flesh, and grew increasingly weaker. When he entered the hospital his conjunctivæ were pearly white, his tongue pale, and his spleen and liver somewhat enlarged. Cardiac dullness was increased in area. The first sound was feeble, the second distinct; his temperature was 98°. There was here marked evidence of anemia, and we asked whether there was any drain on the man's vitality to account for it. There was no diarrhœa, and when we examined the urine there were no actual morbid ingredients; the specific gravity was 1013. Here, then, the only tangible evidence of disease, barring the enlarged liver and spleen, was the very decided anemia. Under these circumstances the question arose as to the cause of the feeble heart and the shortness of breath; were they merely the symptoms of an impoverished condition of the blood, or were they the disease itself? Now comes in a very important point; Dr. Penrose made an accurate count of the red blood corpuscles, and found them reduced three-fourths—that is to say, where there would have normally been four there was only one, and while well formed, they were noted to be pale. While the white corpuscles were diminished, they were lessened only in proportion to the red. The heart, lungs, liver, spleen, and kidneys were repeatedly examined with negative results, so that we were compelled to accept the condition of this man's blood as the explanation of his condition. As the spleen was enlarged, we looked upon this blood deterioriation as related to that organ; and as the patient comes from Southern Italy, where malaria is very prevalent, we were caused to look upon malaria as the producing factor.

He is still, as you see, anemic, but nothing like he was. He has now some color in his lips, and his tongue (which was pale) is now red. The first sound of the heart is much improved; it now has some weight, and there is no murmur even at the base. The spleen has diminished somewhat in size, though the liver remains about the same. He has never had any marked dropsy, though there was some slight œdema of the feet when he first came in. His lungs are clear on percussion, the respiratory murmur is marked on the right side, and a little feebler on the left. Posteriorly, there is nothing about the lungs to attract attention. His urine now has a specific gravity of 1020, there is no albumen, and he now passes one pint more in twenty-four hours than when he first came in. But the most striking point about the case is that so much has he improved that his blood now contains three-fourths of its normal amount of red corpuscles. The treatment that has brought this happy result is a matter of great importance. At first he was given five drops of Fowler's solution thrice daily, which has all along been continued; later, he was given a salt of iron, a partial double salt of sodium, and the pyrophosphate of iron, ten grains thrice daily. This was borne well; it did not irritate the stomach, nor constipate the bowels, though it is a big dose. This case is very interesting, both from a diagnostic and therapeutic point of view. From the diagnostic point we may contemplate what symptoms anemia may produce, how, when the condition of the blood is impaired, all other organs and functions may suffer, and how, when it is improved, they correspondingly improve. From a pathological view the etiology may arrest attention. I think the cause was malaria, but the spleen is not sufficiently enlarged to warrant me in calling it a case of decided splenic anemia; it is not due to faulty nutrition or starvation, for the man is fairly well nourished otherwise. I incline to think, therefore, that it was most likely due to malaria and the enlargement of the spleen, which we know is an important blood-making organ. When the red corpuscles are reduced, as here, from four to one, we have to deal with an extreme case. The therapeutics of this case possess more than usual interest. Arsenic is a decidedly good remedy where the blood is impoverished; it is one of our best nerve tonics, and where the blood is altered with some poison behind this alteration, and especially if this be of the nature of malaria, arsenic is invaluable. In ordinary anemia it is also a good remedy, for it always rather tends to improve the condition of the blood, to increase the red corpuscles, but especially is this so when the nervous or glandular systems are involved, particularly if the cause be malaria. We have also here derived very remarkable benefit from the use of iron. This form of iron is but little used as yet, and I might almost say that its external use originated in this house. I was experimenting to find a soluble salt of iron, that would not be irritating for hypodermic use, when I hit on this. The only clue I had was from a statement in a German medical journal that a salt formed by the addition of sodium to some salt of iron might be thus used. I went further, and got the salt

I have introduced to you. It has been made officinal in the last pharmacopœia. Having used it hypodermically with perfectly satisfactory results, I conceived the idea that it might be given internally, and I have been very much pleased with its use thus. It may be given to children, and it is extremely well borne. The dose will be from five to ten grains in solution in water. It does not irritate the stomach, and does not constipate —at all events, not nearly so much as any other salt of iron. We will now discontinue the arsenic, but keep on with the iron.

Acute Endocarditis.

Here is a colored man, 23 years of age. Six years ago he had an attack of rheumatism that confined him to bed for eight weeks, so it must have been a real severe attack. From this he recovered, and was perfectly well until two weeks before his admission to the hospital, when he again had rheumatism of the knees, shoulders, and wrists. He was admitted to the hospital December 28, when his temperature was 100, his pulse 96, his tongue coated, costive, knees swollen and painful; urine, sp. gr. 1030, containing an excess of uric acid, but no albumen. His heart was examined at this time, and *there was no murmur.* At once, on the very first day of his admission, he was given ninety grains of salicylate of sodium. This treatment was continued until the 1st of January, at which time there was no fever and no pain. The salicylate was now stopped, and he was given quinine. Though the pains in his joints were gone, he complained of uneasiness and pain about the heart, and on the 8th of January a *soft systolic murmur was heard at the apex.* Remember that the heart had been examined daily, but this murmur was never heard before. He was now given one ounce daily of bicarbonate of sodium, which he bore well, but the murmur still persisted. Here was an attack of acute endocarditis, affecting principally the mitral valve, developed while the man was under observation. It is noted on the 15th that the murmur is still distinct. The alkali since the 12th has been reduced to half an ounce daily, because the urine was found to be alkaline. The temperature this morning (January 23) is 99°, towards which point it has been slowly declining. There have been many variations; on one occasion it arose to 103°. There is now no pain on pressure over the cardia, there is no shortness of breath, his respirations are 24; but there is, to-day, a distinct but not harsh systolic murmur at the apex, followed by a second distinct sound. The impulse is well marked, and there is no increase of cardiac percussion dullness. In the lungs, posteriorly, the respiratory murmur is rather feeble, especially on the left side, but there is no marked dullness. His pulse is only 64. Throughout the whole course of the disease his pulse has been curiously slow; taking the 6th when it was only 54, it has varied from this to 60, 62, 64, 58, 68, 60, 56; only once it rose to 90, which was a very temporary rise, as it was down again the same evening to 80, and the next day to 60. This pulse is the more remarkable because there has never been any pericardial effusion to interfere with the action of the heart. This is a curious case; years ago the man had rheumatism from which he recovered without any damage to his heart; there was no heart lesion when he came in here, but the lesion actually develops under observation, when the joint symptoms have subsided. Another curious feature is that a lesion affecting a valve so important as the mitral, of origin unquestioned, has existed without any acceleration of the circulation, in fact, the pulse is really slower than normal. This case tends to confirm me in the conviction that has for some time been growing on me, that the salicylates are useless, in so far as they are expected to prevent cardiac complications. Do not misunderstand me—their value is great and undoubted in rheumatism, but they will not prevent the occurrence of cardiac lesions as sequelæ of rheumatism. What treatment have we then that is better? Unquestionably, the alkaline treatment. Where, in the treatment of rheumatism, we note the least tendency towards heart complication, we should use alkalies, which are better than the salicylates, not only to prevent the heart lesion, but also to cure the rheumatism. Fuller first advised us to saturate the system, giving half an ounce or an ounce of bicarbonate of sodium in twenty-four hours; after a short time the urine will become alkaline, and we can then diminish the dose. The alkalies defibrinate the blood, and prevent deposits on the valves. Now the question arises whether this man is going to recover entirely, without any permanent heart lesion. It would be premature to formulate a positive opinion on this score. I believe, however, that he will get well without any marked cardiac disease, for the murmur is so very soft. There may be some little permanent roughening. Now the time has come in his case to give iodide of potassium, which we will do in doses of ten grains thrice daily, and we will reduce the bicarbonate of sodium to two drachms

thrice daily. His diet will consist of milk, broth, farinaceous articles, arrow-root, oysters, and but little meat. He will have no stimulants, and will get eight grains of quinine daily, which I think has a tendency to prevent relapses in rheumatism.

Pilocarpine in Erysipelas.

I bring these two cases before you to illustrate the great value of pilocarpine in the treatment of erysipelas. In the first case there was erysipelas of the leg and face. He was given one-sixth of a grain of pilocarpine by hypodermic injection; two hours later he was given one-eighth of a grain, and was purged with a mercurial pill. But he did not sweat freely. He was then ordered twenty drops of the fluid extract of jaborandi every two hours, when he did sweat, and the disease was checked in twelve hours after the first hypodermic; the temperature went down to normal, and he made a rapid convalescence from that time. He is now taking twenty drops of the fluid extract thrice daily; he still sweats, and his urine has increased from two and a half to three and a half pints in twenty-fours hours. The drug did not have sialogogue effects, nor did it seem to have any action on the heart. The second case is one of erysipelas of the nose. On admission, the temperature was 103½°. After the injection of pilocarpine, it fell to 100°, later to 99°, and has never since been up to the fever temperature. Neither of these patients have had any iron or quinine. This pilocarpine treatment grows on me as one of great value. I believe it is more especially useful in erysipelatous affections of the face, in those who are not feeble, and where we have no need to fear exhaustion.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. Roberts Bartholow.

Melancholia with Illusions.

This woman, who is forty-nine years old, has been afflicted with melancholia for some time, and her case affords us the opportunity for some interesting studies. She worked in a match factory, but not among the phosphorus, as she was employed in the box-making department. The first symptom of her present trouble was a loss of memory; she found herself only able to count the boxes with difficulty, and when counted she would forget the number. Following this came depression of spirits and apprehension for the future, a dread of poverty, and the like. Then supervened wakefulness, born of a fear to go to sleep, lest she might die in her sleep; so that she would resist the inclination to sleep, thus working the double injury of mental strain in endeavoring to keep awake, and the necessary exhaustion from the want of sleep. With this wakefulness came illusions; she would hear voices, not from any particular locality or person, but she would hear, at night, conversation. This is a point in connection with melancholia that requires your deepest attention, for when these poor creatures "hear voices," they will sometimes hear "a voice from heaven" commanding them to commit murder or suicide, and such commands are not infrequently obeyed. This woman sees strange external objects; she will see persons and things in trees, which, for a time, seem real to her, but, by a process of reasoning she is able to convince herself that they are not material, but only illusions. Let me draw for you the distinction between an illusion, a delusion, and an hallucination. An illusion is the perversion of an object really seen, as in this case the woman really sees a tree, but she perverts it by her disordered cerebration into a person or something other than a tree; when one imagines that he sees something when he sees nothing, when he has no foundation for his imaginary object, it is an hallucination; and when he cannot, by reason, disabuse himself of his illusion or hallucination, then it becomes a delusion. According to lawyers, delusions are proof positive of insanity. In this case there is no delusion, because the woman can, by reasoning, convince herself of the illusive character of her perceptions. So, also, with the imaginary conversations; she can convince herself that they are not really heard, and there is also a foundation for them, hence they constitute neither an hallucination nor a delusion, but merely an illusion. This foundation consists in the fact that she has ringing in the ears, which she perverts for a while, at times, into conversations.

We will sometimes observe illusions or may be delusions of taste, when patients will persistently refuse food. Such a phenomenon may have a foundation, as if there be a disordered stomach, and its correction may be under the control of reason, hence it is only an illusion; but it may, on the other hand, have no foundation, based upon the idea that all food is poison, when it is, in reality, a delusion.

Melancholia is a condition of depression, as acute mania is one of excitement. All the bodily functions are depressed, and this

must be taken into consideration in formulating our therapeutics. We must carefully look to outside sources of mischief, as, for instance, the existence of constipation or dyspepsia. Constipation is a very common condition among melancholics, due, in part, to their indifference; it is wonderful how great will sometimes be the accumulation of fæcal matter. The ancients, as we learn from the aphorisms of Hippocrates, thoroughly realized this intestinal torpor, and we have the word *hypochondriac*, meaning under the ribs, as evidencing their appreciation of the rolé of the colon in producing this condition. We should see to it that the bowels of such patients are freely emptied, and we should then direct our attention to vivifying the cerebral functions. Most admirable results will be derived from small (stimulating) doses of opium, and of the various preparations I prefer the deodorized tincture, in doses of from three to five drops, three, four, five, or six times daily; but it must be used with caution, lest it may "vivify too much," and produce an excessive excitement. The same rule will hold good with alcohol; when we wish to use this drug as a stimulant, we should give it on an empty stomach, but when we intend it as a food, it should be taken with or just after the meal. Change of scene and out-door exercise will also be indicated, and this exercise should be directed just at the end of digestion, when the food is about to be assimilated into the blood, and when it will be benefited by an additional amount of oxygen to complete the metamorphosis.

Diphtheritic Paresis.

This boy talks as though his mouth was full of hot mush, and when he takes a drink some of the liquid flows out of his nose. When he walks you notice that he cannot combine the action of the muscles of the two sides with any degree of certainty. You must remember that there is an automatic mechanism and a voluntary mechanism. If you start to walk from here to the river, you put into motion a set of muscles that will work automatically, without any volition or direction on your part. When, however, I tell him to shut his eyes, and, extending his arm, to bring his forefinger to his nose, he brings into play his voluntary mechanism, and this, you see, he can only do with some difficulty. But there is here also some derangement of the unconscious or automatic mechanism, as evidenced by the failure of the veil of the palate to perform its duty, allowing the regurgitation of fluid. He has had diphtheria recently, and we have the sequel of paresis from head to foot. You must draw the distinction between paresis and paralysis, the former indicating only a partial, while the latter means an entire loss of power. If the faradaic current fails, these cases will usually respond to galvanism, which should be employed until the reaction to the faradaic current is re-established. If the muscles fail to respond to galvanism, then we know that the true muscular tissue is replaced by connective tissue and fat, but it is very seldom that we find cases so far gone. It is a singular fact that in many cases the muscles will respond to the stimulus of the will, even before the reaction to the faradaic current is established. The use of electricity serves two purposes; it puts the muscles in use, and improves the circulation. If there is incontinence of urine, an urethral electro may be passed into the urethra, the non-insulated portion being placed at the neck of the bladder, and the other pole over the genito-spinal centre; the same procedure may be used for atony of the bowels. In bad cases I would use the alkaloid strychnine, hypodermatically, one-sixtieth of a grain every day or two or two or three times a week; it will tone up the nervous system. In less severe cases I would give the same drug internally.

℞. Strychnine, gr. $\frac{1}{80}$.
Acid phosphoric dil., gtt. x.
M. S.—For one dose, well diluted, thrice daily.

The general nutrition must be increased, which can be best accomplished, I think, by the use of officinal syrupus hypophosphatum cum ferro.

Stomachic Vertigo.

My hour has so nearly expired that I can do no more than merely show you this man and say that I consider Fowler's solution, in doses of two drops in water, thrice daily before meals, combined with a rigid supervision of diet, as the best treatment for stomachic vertigo.

BALTIMORE GYNECOLOGICAL AND OBSTETRICAL SOCIETY.

Discussion on Labor Complicated by Placenta Prævia. (*See page* 197.)

Dr. B. B. Browne remarked that about ten years ago he had had a somewhat similar experience, the patient also being a colored woman. He was called to a case, which had been attended by a midwife, about twelve hours after the delivery of one child, to de-

liver the other, which the midwife said was fast and could not come away. Upon examination, a sub-peritoneal tumor as large as a fœtal head at full term was found. The tumor had attained this large size during the period of pregnancy. With involution of the uterus the tumor decreased rapidly in size, and at the end of six weeks could scarcely be detected. This case was reported in the *Am. Jour. of Obst.*, vol. x., p. 39.

Dr. Morris asked Dr. Miltenberger's opinion as to the theory advanced in the paper, that the ovum had by a law of selection attached itself to the cervix, not finding a proper nutrient *nidus* in the body of the uterus.

Dr. Miltenberger thought the theory a very plausible one.

Dr. T. A. Ashby asked Dr. Morris whether menstruation had occurred during pregnancy in the case which he had related. Several cases had been reported in journal literature, when menstruation had continued during pregnancy, and the explanation offered was based upon the discovery of polypi and submucous fibroids in the uterus. In the classical case reported some years ago by Dr. L. M. Yale, menstruation was observed in a pregnant woman, and upon examination a very small polypus was found and removed, and hemorrhage did not again occur during pregnancy.

Dr. Ashby was of the opinion that the explanation offered by Dr. Morris to account for the position of the placenta was a most rational one. The presence of the tumor had, no doubt, prevented the ovum from becoming engrafted upon the mucous membrane covering it, and as the tissues about the cervix were in a healthy condition, a favorable site was offered for the development of the decidua and the growth of the ovum.

The doctor then related the following history of a case which he had attended about a year ago. He was first called to see the patient during labor, and learned that she was over five months advanced in pregnancy. For two weeks she had been losing large quantities of blood, but this circumstance had not attracted serious attention until severe labor pains set in. Upon examination he found the placenta firmly attached to the right side of the cervix, but a large portion which lapped over the internal os had become detached. Hemorrhage had resulted from this detachment, and the copious loss of blood had destroyed the life of the fœtus, which had evidently been dead for several days. The breech presented: after some delay in dilating the cervix, delivery took place. The placenta being firmly adherent, was detached with some difficulty. The patient made an uninterrupted recovery. Dr. A. considered that the occurrence of the abortion had proven a conservative process, as the full development of the child would doubtless have led to more serious complications. In this case there was no evidence of a fibroid tumor, but impregnation had followed pretty closely upon the birth of a child, which may have accounted for the occurrence of a placenta prævia.

Dr. Miltenberger said he thought that the presence of an intramural fibroid would not, as a rule, cause hemorrhage during pregnancy, although polypi are very apt to do so.

Dr. Brown asked Dr. Miltenberger if it was not his experience that fibroid tumors increased very rapidly during pregnancy.

Dr. Miltenberger replied that, at the moment, he remembered three cases of pregnancy complicated by fibroid tumors. In two of these there was marked increase in the size of the growth during gestation, and rapid disappearance after confinement. Both occurred in young women.

Dr. W. P. Chunn thought that hemorrhage might be caused by the unequal contraction of different portions of the uterus, due to the presence of the tumor, which might also, to some extent, have prevented the expulsion of the placenta. Dr. Emmet had related a case in which alarming hemorrhage followed the extraction of a submucous fibroid, and was only checked after a second tumor, which was found in the parenchyma, was removed.

Dr. Robt. T. Wilson referred to a patient of his, who told him that the only time she menstruated or had any bloody discharge from her uterus was during pregnancy, but that during that period the flow appeared regularly each month, ceasing after labor had taken place. His patient was a white woman, and had no fibroid tumor.

Dr. Morris believed that hemorrhages during pregnancy did not result from intramural fibroids. As regards the prognosis in these cases, he felt safe in telling the friends that the tumor would disappear.

Dr. Browne remarked that the existence of fibroid tumors in the uterus was a recognized cause of sterility, but when pregnancy does occur in such cases, the tumors increase rapidly in size with the development of the uterus. After delivery, with involution of the uterus, the growths quickly diminish in size and frequently disappear altogether.

Dr. Neale referred to two cases, the history

of which he had read before the Maryland Medical and Chirurgical Faculty.

Case 1. Mrs. A. P., æt. 28, was delivered of her fourth child, after a perfectly normal and easy labor. A teaspoonful of fluid extract ergot was given post-partum, but a considerable bloody discharge with severe after-pains continued for twelve hours, when the patient expelled from her uterus a fibroid tumor, which the doctor preserved. Its presence had not been suspected.

Case 2. Mrs. M., American, æt. 20, was delivered with forceps after a difficult and tedious labor. The uterus, after expulsion of the placenta, although firmly contracted, would not descend below the umbilicus. Both Dr. Miltenberger and Dr. N. made careful vaginal examinations and diagnosticated a fibroid tumor, apparently about the size of a man's fist, in the posterior uterine wall. Nothing of special note occurred until the eighth day, when the patient passed from her uterus a fleshy mass, described by the nurse as being "like a miscarriage, and resembling in consistency the gizzard of a chicken." It was thrown away by the nurse, but both physicians considered the case analogous to Case 1.

Dr. Neale considered these cases especially interesting as occurring in young white women, and thought the fact of spontaneous post-partum expulsion might have some bearing upon the treatment and prognosis.

Dr. Morris referred to a patient of his, who, about eight days after each of her confinements, had passed a fleshy tumor from her uterus. Dr. Miltenberger had kindly attended this patient in one of her labors for Dr. Morris, and had had an opportunity to examine one of these tumors. Dr. Morris has seen notices of similar cases in foreign textbooks, but has never seen them in our own.

CLINICAL SOCIETY OF MARYLAND.

Meeting January 8, 1886.

Discussion on Displacement of the Heart. (*See page* 199.)

Dr. Randolph Winslow wished to know if Dr. McSherry thought a man could have cirrhosis of the lung without having phthisis.

Dr. McSherry—I have stated that this man has phthisis.

Dr. Winslow—Do you think he could have cirrhosis without having phthisis?

Dr. McSherry—He might have a chronic interstitial pneumonia.

Dr. Winslow—You think, then, that he might have cirrhosis without phthisis?

Dr. McSherry—No, I should say he could not have cirrhosis without phthisis; but in making this statement, I wish it to be understood that I make a distinction between the terms phthisis and tuberculosis.

PHILADELPHIA CLINICAL SOCIETY.

Discussion on Perityphlitis. (*See page* 165.)

After the reading of the paper, Dr. James B. Walker said he wished to give special emphasis to the "*doughy*" sensation mentioned by the author. This is a pathognomonic indication of deep-seated pus, in empyema, hepatic abscess pointing towards the thorax, as well as perityphlitis, and is of great value, inasmuch as fluctuation is rarely appreciable under these circumstances. In cases of prolonged effusion in the pleural cavity, when the effusion has become purulent, the "*doughy*" sensation is apt to be found in the thorax, at the most dependent portion, overlying the empyema, and an exploratory puncture should always be made with the hypodermic needle.

Dr. L. Brewer Hall asked whether grape seeds, cherry stones, etc., were necessarily a cause of perityphlitis.

Dr. Hanna T. Croasdale mentioned a case of inflammation which was subacute in character, confined to the right iliac region. The patient became greatly emaciated; hands very thin, almost transparent; there was a feeling of discomfort rather than pain; no febrile symptoms. Under careful taxis and manipulation peristaltic action was set up, causing the expulsion of masses which had been accumulating for months—bits of linen thread, seeds of small fruits and vegetables; some of the tomato seeds had sprouted. Relief came gradually, and there was finally complete restoration to health.

Dr. James B. Walker considered this a case of typhlitis, causing paralysis of the intestinal wall, and allowing accumulation with impaction in the cæcum. He also called attention to the difference in the decubitus between general peritonitis, and localized peritonitis confined to the pelvis. In the former the patient is more comfortable with the thighs flexed, relieving the tension of the abdominal muscles; in the latter, the thighs are extended, because contraction of the psoas and iliacus muscles would add to the pain, instead of relieving it.

Dr. Edward R. Stone referred to the importance of œdema as an indication of pus in serous cavities, and spoke of its importance for the same indication in the subcutaneous tissue of the mammary gland.

Dr. Keen, in closing the discussion, said there was more apt to be œdema in the overlying tissue during the acute stage than when the trouble became chronic.

In a large number of cases there are no seeds present, and even if there were, there is such a gush of pus that everything is swept before it, and it is almost impossible for any seed to be seen. If a pus cavity had been formed in the case mentioned by Dr. Croasdale, manipulation would have *aggravated* rather than *alleviated* the symptoms. Flexure of the thighs is not very common in perityphlitis; still it does occur, and its absence and the absence of fluctuation must not be taken as evidence that no pus is present. When the pus is deeply seated, the overlying colon may give rise to a clear percussion note if the percussion be superficial, but on deep percussion dullness is generally found.

Dr. Charles K. Mills then read a paper on

Catalepsy.

After the paper had been read, Dr. James B. Walker spoke of a case of catalepsy of which he had heard through another practitioner. The patient was a sailor, and when at work on the vessel, drawing rope or any occupation whatever, he would be seized with an attack of catalepsy, and remain in the position he chanced to be in for a few minutes, and then go on with his work. The seizures finally became epileptic.

Dr. Caroline Dodson wished to know in which sex the disease was more likely to occur, also the effect of the artificial production of this condition,

Dr. Mills, in answer to these questions, replied that he considered hysteria and hystero-catalepsy more frequent in women than in men, though he believes the conditions are more frequent in men than they were once thought to be. He considers that the artificial production of the condition is apt to upset the nervous system for a time. The disease is not very common in this latitude; more common in the warmer and tropical climates.

Mary Willits, M. D.,
1527 *Green St.* *Reporting Sec.*

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Meeting, November 12th, 1885.

The president, J. C. Wilson, M. D., in the chair.

Dr. Fussell presented specimens from a case of "Mastoid Disease." Male, æt. 25 years. Never had scarlet fever. Since vaccination, at the age of 5 years, has had occasional attacks of suppuration of the middle ear. General health was good. Was first seen by Dr. F. July 14th. For several weeks he had had earache, with one slight chill. When seen, hearing was very poor, membranæ tympani opaque, swelling and redness over left mastoid process, and temperature elevated. His general condition grew worse, and an incision was made over the mastoid process, but it failed to find pus. On extending this incision a few days afterward, pus flowed freely and he was much relieved. He afterward grew worse, fell into a typhoid condition, and died July 24th. Before death blood oozed freely from the cutaneous surface. At the autopsy the mastoid cells were found filled with pus. In the inner half of the process was a large irregular cavity filled with a pultaceous mass of necrosed bone; this communicated with the middle ear. The walls of the lateral sinus were thickened, easily detached from the bone, and the seat of a purulent inflammation. The sinus contained no thrombus. The meninges over this spot were discolored, though not inflamed, but there was a patch of inflammation over the anterior edge of the left lobe of cerebellum. Brain substance was normal. Remaining organs were not remarkable, except the right lung, which contained in its apex two small abscesses. From the condition of the sinus, the reporter thought there had been an actual admixture of pus with the blood.

Dr. Packard presented an "Anomalous Lung." It was taken from the body of a negro who died of Bright's disease. From the inferior surface of the lower lobe of the right lung springs a tongue-shaped process of pigmented, crepitant lung tissue, 2½ inches long and 2 inches wide at its base, resting upon the diaphragm, its upper surface being in apposition with the under surface of the lower lobe. Dr. Packard had recently seen in the body of another negro a similar anomaly, except that the process was smaller and situated more anteriorly.

Dr. Musser presented a "Cystic Kidney." It was the right kidney, and was taken from the body of a man, æt. 72 years, who died of apoplexy. The kidney was cirrhotic, and it contained two cysts, the larger occupying the upper one-fourth of the organ. Its walls were firm, and contained clear fluid, in which floated cheesy masses, which the reporter thought were degenerated pus. When first seen the patient was passing small quantities of bloody,

highly albuminous urine, and complained of pain in the right renal region. These symptoms were apparently due to an acute process grafted upon the chronic lesion. The blood and most of the albumen disappeared, but the pain persisted. Was this pain due to the cyst?

Also, a "Carcinoma Mammæ," removed from the body of a woman, æt. 75 years. The breast had been injured eight years ago, and three years afterwards the tumor was noticed. There was never any pain in the tumor. The lymphatic glands of the axilla were involved. In addition, there was a large lipoma of the back of the arm. She had frequent attacks of severe pain in the tibia and left parietal bone, apparently due to periostitis, and not to any secondary growth. There was no syphilitic history.

Also specimens from a case of "Diabetes Mellitus." Female, æt. 43 years. Had a vesico-vaginal fistula 14 years. Diabetes had existed, without apparent cause, two months. Patient was unusually fat, and had lost no weight. She died of coma. Temperature in the abdominal cavity three hours after death, was 107.8° F. Liver large and fatty; gall bladder contained 30 stones. Kidneys fatty. Pancreas normal. Blood had a most marked lactescent appearance, and after standing 12 hours globules of fat collected on its surface. Lacteals in the mesentery engorged with chyle. Microscopic examination of lungs showed no fat emboli. In the the urinary bladder was a large phosphatic calculus. Dr. Osler thought the peculiar condition of the blood was what we should find normally in a person dying during digestion, and called attention to the fact that very frequently in diabetes there is engorgement of the lacteals.

Also a "Fœtus Papyraceus." The mother was delivered in the morning of a mature living child and in the evening of this fœtus. It is apparently of the fifth month of pregnancy, and with the exception of shriveling and paling of the skin is quite normal. The cord is thin and soft, its length unknown. The placenta is thin, flat, compact and whitish-yellow, apparently having undergone complete fatty degeneration.

Dr. J. B. Roberts presented a small tumor, the size of a hickory nut, which he had removed from the back of the wrist of a young man. It had the clinical appearance of an ordinary ganglion, but attempted evacuation showed it to be solid. It was then enucleated and found to have been developed within the theca of the tendon going to the middle finger, and probably between its fibres. The great rarity of solid tumors in this locality was mentioned.

Dr. Osler asked if the patient had a rheumatic history, although his specimen was rather large for a subcutaneous nodule occurring in rheumatism.

Dr. Roberts knew nothing of the history.

Dr. Nancrede presented "Fluid from an Encysted Hydrocele." The fluid contained large numbers of dead spermatozoids.

Dr. Hughes presented a "Primary Carcinoma of the Liver." Female, æt. 58 years. A daughter died of cancer of the uterus. She had been in good health till eighteen months ago, when flesh and strength began to fail, and with this there were occasional attacks, lasting about a week, of headache and sick stomach, followed by diarrhœa. There was pretty constant lancinating pain in the hepatic region. Five months ago she had an attack of jaundice (her only attack), lasting two weeks, and at this time a tumor was detected in the liver. At the autopsy, the liver was found much enlarged, and scattered through its substance were firm cancerous nodules, varying in size from an orange to a pin's head. In addition to these, there were several cysts, one in the left lobe two inches in diameter, filled with clear fluid. The liver substance between the cancerous nodules was normal. The gall-bladder was full of healthy bile and the ducts patulous. There were no enlarged glands in the fissure of the liver, but the retro-peritoneal and mediastinal glands were increased somewhat in size, and the seats of secondary deposits. With these exceptions, there was no growth outside the liver. The intestines were crowded into the left side of the abdomen by the enlarged liver. The stomach was very small, only one inch in diameter at its fundus. There was an intussusception three inches in length at the ileo-cæcal valve, which, on being reduced, which was effected with some difficulty, showed the apposed surfaces of peritoneum covered with lymph.

Dr. Formad presented specimens and read a paper on "An Analysis of 250 Autopsies on Drunkards," illustrating the most prominent anatomical lesions of chronic alcoholism. He considered the most conspicuous lesions to be cyanotic induration of the kidneys, fatty infiltration of the liver, and mammillated stomach. His cases had been those in which there had been a history of a long-continued series of debauches, the subjects often dying in one of these debauches, and did not include moderate drinkers or those who perished after imbibtion of an

enormous quantity of alcohol without any previous chronic excesses. He thought that the exposure, irregularities of diet, etc., incident to a state of drunkenness had much, probably more than the alcohol itself, to do with the production of the lesions, but it was not at all possible to separate one from the other. He gave a long list of lesions considered by various authors to be results of chronic alcoholism, among which the cirrhotic liver, with contraction, held a prominent place. He had himself at one time considered cirrhosis a very frequent if not almost necessary concomitant of long-continued excessive use of alcohol, and had even testified in court that a certain person was not likely to have been a hard drinker, because at the autopsy no cirrhosis of the liver was found. He had thought, too, that the connection between the two was so close that it was impossible to have a case of cirrhosis without a previous history of alcoholism, as is held by various authors. Therefore, it was surprising to him to meet in his 250 autopsies with only 6 cases of cirrhosis of the liver with contraction. In 220 cases the liver was considerably or even very much enlarged, the enlargement in most cases proving to be due to a fatty infiltration. Cyanotic induration of the kidney and chronic gastritis, with mammillation of the stomach, were found in nearly every case. This cyanotic induration is peculiar, and different from the cyanotic induration due to heart disease. At a future meeting, he will give a detailed account of the above lesions, and a more extensive analysis of the cases.

Dr. Tyson could not speak from a systematic observation of a large number of autopsies in the cases of confirmed drinkers, but he remembered distinctly being surprised in several cases by the absence of cirrhosis where he confidently expected to find it.

Dr. Wilson said that Anstie, in the article on "Alcoholism in Reynolds' System of Medicine," had called attention to the comparative infrequency of contracted liver in confirmed drinkers. This observer, in an extensive out-patient practice in London, had seen large numbers of cases of alcoholism, but very few among them presented the physical signs of cirrhotic (contracted) liver. The experience of the staff at Blockley Hospital sustains this view. There many of the patients are soaked with alcohol, but even among those whose death is directly or indirectly due to alcoholic excess, fatty liver is much more common than contracted liver.

Dr. Osler thought the experience of pathologists and morbid anatomists, with histories of patients, is not of the most satisfactory character, he often having had cases to dissect where he knew very little of the history. Before saying these cases were chronic alcoholics, Dr. Formad should present more specific statements about them. His own experience with livers, in a large number of autopsies on cases of chronic alcoholism, had led him to divide them into four classes:—1. Those in which the condition of the liver is pretty satisfactory; some of these cases may take alcohol for many years and yet the liver pass muster; (2) Fatty cirrhotic livers; the cirrhosis may not, perhaps, be distinct to the naked eye, but plainly shown by the microscope; this is the largest class; (3) Hob-nail livers; these he would say were much more common than in Dr. Formad's series; (4) Hypertrophic cirrhotic livers. The difference between his observations and those of Dr. Formad might possibly be accounted for by a difference in the form of alcoholic beverage taken. He had not observed the special form of kidney described by Dr. Formad. In reply to a question, he said in order of frequency he would place them, fatty cirrhotic, hob-nail, hypertrophic, cirrhotic, apparently normal.

Dr. S. Solis-Cohen said there were certain theoretical considerations which suggested themselves in this connection. The text-books teach that the lesions of alcohol are of two kinds, sclerosis and steatosis. It is known that in some organs the fibrous change precedes the fatty one. The latter is the higher grade of degeneration. The subjects of Dr. Formad's autopsies were confirmed whisky-soakers, in whom one would expect to find more intensity of degeneration than in those whose use of alcohol, though persistent and excessive, was not so outrageous. Another point which had not been alluded to, was the fact that some lesions might result from a local action of the poison upon the tissues—while others might be due to its systemic action. No study of the subject could be complete in which these points were overlooked.

Dr. Randall suggested that the point touched upon by Dr. Osler—the character of alcoholic beverage—might be very important. In Vienna, among the beer-drinkers, he had found the fatty liver much more common than the cirrhotic, while in England, where much gin is drunk, and he should suppose in Scandinavian countries, where they drink altogether strong spirits, the cirrhotic liver is doubtless comparatively frequent.

Dr. Musser had recently had to go over the records of the Pathological Society, es-

cially in liver diseases, and had found the total experience of different observers the same as Dr. Formad's, and also in those cases cirrhosis was caused not so much by heavy drinking as persistent drinking of spirits, and on an empty stomach.

Dr. Formad presented the "Sac of an Extra-uterine Pregnancy." The woman from whom this was removed had not suspected that she was pregnant. She was in perfect health till twelve hours before death, when she was suddenly seized with excruciating pain in the left groin, rapidly followed by collapse. On opening the abdomen, it was found to contain at least a gallon of partly clotted blood. About the middle of the left fallopian tube was the sac, with a rent in its posterior wall. This sac was one inch in diameter, and contained clotted blood and placental tissue. The uterus was twice its normal size. The fœtus was not found.

Also "An Aneurism of the Ascending Aorta Rupturing into the Pericardium." The patient was a laboring man, and had considered himself in perfect health. He died very suddenly. The aneurism, one-half inch in diameter, was situated just above the posterior aortic leaflet, and had broken through the wall of the aorta at the point where it touches the descending cava. The cavity of the pericardium was fully distended with clotted blood.

Periscope.

Cases of Congenital Malformation of the Eyes.

Dr. F. Richardson Cross thus writes in the *Brit. Med. Jour.:*

Symmetrical Microphthalmos.—F. L., a female child, four months old, was brought for my opinion as to its power of sight. The child was well grown, the head and face well shaped. The orbits were fully developed, but the lids were small and lay deep in the orbit, giving an appearance as if each globe had been enucleated. The lids were usually closed; when open, a mere chink existed between them. This chink (the palpebral fissure), when more closely examined, was of a good length from side to side, the external canthus being drawn inwards to some extent; the lachrymal passages were well developed, and the caruncle fairly large. Under the lids, imperfect eyes could be recognized, moving sluggishly in the direction of a light, or of objects, or of the mother's voice; and small dark corneæ appeared between the narrow palpebral fissures. There was a distinct tendency to inward squint. The movements of the eye were cramped, but the globes could roll fully from side to side. The lids were separated with some difficulty, the rim of the palpebral fissure being somewhat tense, and with scarcely any vertical separation. Healthy conjunctiva covered much contracted symmetrical eyeballs. The cornea in each had a diameter of two lines, and projected in front of the rest of the globe in natural proportion. A complete blue-grey iris, with pupil, existed in each eye. No further definite examination could be made. But the child seemed to possess very small eyes, of which the various constituents were all atrophied, and in due proportion. Four elder children had been born, quite healthy in every respect, except the third, who died when ten months old.

Dr. Fairbanks, of Wells, writes that, when this third child was born, "the orbital cavities were so small, and the lids so rudimentary, that it was impossible to discover anything resembling an eyeball." He adds: "I have seen the last child, and it is in quite a different condition."

When the third child was about two months *in utero*, the mother was very much frightened by an old tramp, who came into her shop and threatened and abused her. This old woman had peculiarly small and sore eyes, which made a great impression on Mrs. L. the whole time she was carrying the child. When the child was born without eyes, the mother at once attributed it to the effect produced on her by the old woman. I consider, from a recent examination of L., that the eyes are growing larger, and the power of vision is somewhat improving. Several cases, both of congenital absence of the eye and of its atrophy, have been put on record; but the microphthalmos seldom seems to be symmetrical, nor is the eye usually so perfect as in this case, whilst the apparently complete anophthalmos of the earlier child adds to its interest.

Irideræmia.—The subject was Daisy C.,

aged two years, a well formed child. The palpebral aperture was narrowed, a broad fold of skin passing from the upper to the lower lid, hiding the caruncle. There was constant rolling nystagmus, the eyes were well shaped, and perhaps rather small. The child looked towards shining objects (watch, silver pencil-case), but without any power of fixation. It was said to find its way about the nursery, avoiding obstacles; and it was believed to recognize jam on bread, and to choose this in preference to butter; but the power of vision was much impaired. The eye did not seem particularly over-sensitive to light. The cornea, sclerotic, and globe of the eye, appeared perfectly normal. The iris was entirely absent. Eserin used for several days gave no appearance of an iris; but, without any leading question from me, the father, who is a most intelligent man, volunteered the information that the child had been holding objects more closely to the eye. This statement might be of importance as showing the presence of the ciliary muscle.

Direct examination with the ophthalmoscope showed a perfectly clear red rim round the lens. The lens appeared cloudy in places, according to the direction of the mirror; and the shadow passed in every direction, as in myopia. The fundus was pale red, with well defined retinal and choroidal vessels. The discs appeared white, with irregular edges, the vessels in the neighborhood being tortuous. There was no posterior staphyloma, nor atrophic patch. The appearance suggested a former neuritis, but was such as is not unfrequently seen in hypermetropia.

I will not trust myself to speak of the presence or absence of the ciliary processes in this case, as I find no special note of it, and have had no opportunity of repeating the examination. Some authors allege that these processes can be clearly seen in cases of irideræmia; whilst others, on the contrary, assert that they are absent. Their absence is rendered probable by the fact that they are developed with the iris from the front part of the outer layer of the optic vesicle blending with the mesoblast which partly passes in front of the lens to form the iris, and partly becomes bent back at the lens-periphery, to form the ciliary body and the pars ciliaris retinæ; whilst the ora serrata is the developed anterior edge of the inner wall of the optic vesicle.

As I am credibly informed, the mother, who had given birth to two other healthy children, asked, directly this child was born, about its eyes; she expected something wrong; for she had been frightened at two months by a dog biting her, and a little later by the man-cook, who was trying to stab a servant in the kitchen. In each case, the staring eye was the main impression made upon the mother's mind.

Rare Case of Intestinal Malformation.

Dr. E. P. Hurd thus writes in the *Boston Med. and Surg. Jour.*, 1885:

Mrs. A. B., of Newburyport, while temporarily staying in Boston, gave birth in May, 1884, to a male child which was found to have an imperforate anus. Dr. H. M. Jernegan was called in to render surgical assistance; he dissected upwards in the ischio-rectal fossa in the direction of the rectum for some distance without finding the bowel, gave up the search, and closed the wound. The next day the infant began to pass thin fæces with its urine, every such passage giving pain. The child seemed for a time to thrive; had frequent fæcal motions per urethram, attended with much straining and distress. At the age of five months, symptoms of obstruction of the bowels set in; for five weeks nothing but urine was passed by the urethra; the abdomen was tympanitic and painful; for several days all nourishment was vomited, these symptoms all passing away with the return of copious fæcal discharges along with the urine.

I first saw the child in October. It was then a puny, pale, delicate infant; weight, fifteen pounds; lay most of the time like a limp, flaccid body in its mother's arms; could not raise itself or sit erect; took its food from the bottle with avidity, and seemed at times playful, but had frequent straining urethral passages of thin fæces, which were generally of a normal color, and curdy.

In the spring of the present year, I found the condition of the infant not materially changed. There had been little growth; there were no teeth. The pain during a fæcal operation was very great, the child writhing in agony. These discharges were quite frequent, averaging one an hour, day and night. The indication for anodyne treatment was urgent, but opiates were, for obvious reasons, unadvisable. I directed that the bowels should be kept free and the stools liquid by manna and magnesia, and the pain relieved by hyoscyamus, conium, chloroform water, and ether inhalations. The consent of the family to a surgical operation (left lumbar colotomy, or opening the bladder at its lower posterior portion and establishing a fistulous communication with the

exterior through an artificial anus), could not be obtained. August 1st, the child sank from the prostration of the hot weather and teething, dying at the age of fifteen months. The autopsy was performed by Dr. H. F. Adams and myself, only the abdomen being examined. The intestinal canal was normal except at the lower portion; there was entire absence of the rectum, and the descending colon, with its sigmoid flexure dilated and distended, and forced over to the right side like a letter V, opened by a narrow, rigid tube an inch and a half in length by half an inch in diameter, into the prostatic portion of the urethra, just behind the pubic arch. The bladder, which was not at all dilated, and to all appearances was healthy. contained a quantity of liquid fæces. The urethra was injected, swollen, and dilated to such an extent that a good-sized catheter could easily be made to enter the bladder, Nothing abnormal was detected in the other abdominal organs.

Such cases as the above have a physiological as well as a medical interest, and seem to be a reversion to a primitive type of vertebrate life.

Discussion on Cholera in Barcelona.

In a paper read before the Barcelona Academy of Medicine by Dr. Sordé, giving his views on the lessons to be learned from the experiences of the recent cholera epidemic, the question of abortive treatment was entered into. When, during the existence of cholera, cases of diarrhœa occur, with frequent fluid stools and little or no pain, energetic treatment should be at once adopted. Laudanum should be given, and strict confinement to the bedroom enjoined. If there is frequent vomiting and severe gastric pain, drugs by the mouth are useless; so probably is medication per rectum; and even the absorbent power of the skin is often so slight that external applications are of little efficacy. The only plan then is to resort to hypodermic injections. The most useful drugs are the salts of quinine, amongst which the author prefers the hydrobromide. Ether also is useful for setting up reaction. Subsequently tonic medicines may be given. The best nourishment for cholera patients is at first vegetable soup (in the case of children, Nestlé's milk food); afterwards meat soup without fat, and milk, and ultimately solid food, may be allowed. Cold water the author considers indispensable in all stages. He does not allow alcohol until convalescence. With regard to diagnosis, the author considers it impossible to diagnose cholera with absolute certainty unless the algide stage is reached. As to prognosis, he considers cholera less fatal than typhoid. In the discussion which followed, Dr. Suñé remarked that until the outbreak of this epidemic he had always considered that at such times diarrhœa should be looked upon as a premonitory symptom of cholera, but that now he knew that numbers of cases had occurred in Barcelona, which had got well by themselves, so that if all had been treated with opium the drug would have been credited with far too great a degree of efficacy. He referred to the case of a student who, being attacked by diarrhœa and having great faith in the ideas of Tunisi, took enough laudanum to render him narcotic; notwithstanding which cholera developed itself. Dr. Carré also believed that the efficacy of laudanum had been over-rated, and referred to the case of a boy whose uncle had dosed him well with it, but who, nevertheless, developed all the symptoms of cholera. Dr. Fargas mentioned some observations he had made on the body of a man who had died from cholera which lasted only a few hours. Nothing remarkable occurred during the first hour after death, but at the end of that time movements were noticed in the legs, shoulders, and head, also fibrillar contractions in the arms. The temperature had risen to 40° C., and sweat was observed on different parts of the surface.

Abnormal Mobility of the Tongue, with Ability to Project into the Naso-Pharynx.

Dr. Louis Jurist records this case in the *Med. Record*, 1885:

Thos. P., aged twenty-one, syphilitic, was referred to the Throat Department from the Surgical Dispensary of the Jefferson Medical College Hospital for examination. He had suffered for thirteen years with chronic rhino-pharyngitis, and had been much annoyed by the accumulation and desiccation of mucus in the naso-pharyngeal cavity and on the posterior wall of the pharynx. He often examined his throat with the aid of a hand-glass, and two years ago succeeded, after two months' practice, in reaching his pharynx with the tip of his tongue and removing the masses of secretion. This procedure now became a source of much comfort, and was indulged in daily. On one occasion his tongue slipped into the pharyngeal vault, and gave him still better facilities for cleansing. Upon examination, the evidence of an ordinary inflammation of the turbinated tissues, with hypertrophy and subsequent

pharyngitis, was well marked. He could with the greatest ease, and many times in succession, project the tip of his tongue into the vault, and described fairly well the posterior extremities of the inferior turbinated bones, the posterior septum, etc. A probe passed through the inferior meatus was readily and freely moved.

The frænum linguæ was ruptured in three or four places, and he stated that the under surface frequently felt sore, and that he often heard "cracking" while practicing. His tongue, rather pointed, was not of unusual length. Nothing abnormal in the conformation of the naso- or oro-pharynx could be detected. As far as I have been able to discover, but three similar cases are on record.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a little duodecimo translated from the French of M. F. Sarcey, the author, under the title "Mind Your Eyes," gives a variety of advice to near-sighted persons as to the proper methods of using their eyes. The advice does not impress us as always sound, but the style is pleasant and amusing.

——Dr. Leopold Casper, our esteemed correspondent in Berlin, sends us the reprint of an article by him contributed to the *Berliner Klin. Wochenschrift*, in which he reports a number of cases of extremely obstinate gonorrhœas cured by the cannellated sound.

——"The Hygiene of Pregnancy" is the title of the address of Dr. S. C. Busey, President of the Obstetrical Society of Washington. The subject is discussed in an able manner.

——The report of the proceedings of the Illinois State Board of Health, at its annual meeting last month, makes a pamphlet of 66 pages. It contains discussions on a number of matters of interest.

——Under the title "The Essentials of the Physical Diagnosis of Thoracic Diseases," Dr. E. D. Hudson, Jr., of New York city, has issued a brief treatise of 63 pages, giving a synopsis of the leading points in this branch. It was prepared for the use of physicians attending the post-graduate course at the New York Polyclinic, and seems well adapted to the purpose.

——In a reprint on the extraction of foreign bodies from the nose, Dr. D. B. Delavan, of New York city, offers a suggestion which we have not previously seen, and which merits quotation. It is as follows:

"To remove the foreign body, first cleanse the mucous membrane anterior to it. Then apply thoroughly to the membrane a four per cent. solution of cocaine, repeating the application if necessary after the lapse of about five minutes. The engorged and thickened tissue will quickly retract, and the passage thus having been widened, the body will often be extruded by simply blowing the nose. Should it still be so firmly impacted as to require the use of an instrument, its removal will be greatly facilitated by the anæsthesia of the parts, as well as by the additional space provided."

BOOK NOTICES.

A Manual of Auscultation and Percussion. By Austin Flint, M. D., LL. D., etc. Fourth edition. 8vo., cloth, pp. 280. Lea Brothers & Co., 1886.

This convenient synopsis of the art of physical diagnosis, as applied to thoracic diseases, has evidently met the wants of the profession, as is shown by the appearance of the fourth edition. It has undergone a careful revision at the hands of the author, and various additions may be noted which add to its utility. One of the most important of these is the insertion of diagrammatic illustrations, which set forth to the eye the different areas with their corresponding physical signs.

Fractures and Dislocations. By T. Pickering Pick, F. R. C. S., etc. Illustrated. 12mo., pp. 524. Lea Brothers & Co., 1886.

We have before referred to the series issued by Lea Brothers & Co., entitled "Clinical Manuals for Practitioners and Students of Medicine." All the volumes of the series are characterized by a thoroughness of preparation which is by no means universal in such extended publications. The present one is no exception to the rule. It is a concise and practical treatise on fractures and dislocations, largely resting upon the personal observations of the author. The contents are divided into four parts, treating respectively of the general pathology of fractures, special fractures, general pathology of dislocations, and special dislocations. There are quite a number of illustrations, and the volume, like all of the series, commends itself for convenience of size and excellence of manufacture.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

HOW LONG DOES THE HEAD OF A DECAPITATED PERSON RETAIN SENSIBILITY?

The *Revue Méd.*, 8, 1885, publishes an interesting report of an exciting debate which took place in the July meeting of the Biological Society of Geneva. Drs. Reynard and Laborde communicated to the Society the experiments which they had made on the body of a criminal immediately after decapitation. R. had paid attention mainly to the headless body; he observed the well-known fact, that immediately after the execution all the muscles responded to the faradic stimulus; three minutes later all contractions suddenly ceased, and all reflex excitability was at an end. L., who had occupied himself only with the head, was less positive. He believes that it is by no means certain that insensibility is at once lost, for he found the pupillar reflexes retained for several minutes after decapitation. The excitability of the cortical layer of the cervical spinal cord was retained for twenty-two minutes after death. To determine whether by injection of defibrinated ox-blood, or by direct transfusion from the carotids of a living dog, the excitability might be reëstablished after the twenty-two minutes, he made the experiment and obtained contraction of the facial muscles up to the fiftieth minute.

Paul Bert was greatly opposed to all experiments of this kind, for, as he said, if they do not succeed we do not learn anything from them, while if they do so we are not justified to perform them. L., on the contrary, maintained that the question was an important one, for if it could be demonstrated that the head of a decapitated person was still capable of sensation, that form of capital punishment would forever be stricken from the criminal code.

Herzen threw a different light upon these researches by saying that while in Schift's laboratory he had made experiments to reestablish the circulation of decapitated animals by introducing fresh blood into the cerebral vessels. As a result, he came to the conclusion that *all* functions of the brain, therefore also the whole physical existence, even after a complete interruption of these functions for several hours by a perfect anæmia, would be reawakened by reëstablishing the circulation of the blood under conditions as much as possible resembling the normal ones. He is fully convinced that if the experiment could be made on the human head, even a few hours after decapitation, the same result would be obtained; but he believes the procedure to be an inexcusable and barbarous one, and that the determination of no

scientific question could ever justify any physician in carrying out such an experiment.

We may add that some of the observations mentioned in the discussion were made sixteen or seventeen years ago by Prof. W. H. Pancoast, who tried electro-muscular contractility on the body of the murderer Probst, immediately after it had been cut down from the gallows. If we are not mistaken, the muscles retained their response to the faradaic stimulus for over an hour; and we still remember the horrible spectacle, when the facial muscles, including the eyelids, contracted under the same stimulus, the countenance almost resuming the play of the living features. All that was gained at that time was the demonstration of the fact that the muscles of a person who had died the death by hanging retained their electro-muscular contractility for over an hour, for nothing new was elicited, that fact having been established and well known at least twenty years before. All such useless experiments, as they generally penetrate to the general populace, can only augment superstition and promulgate wrong ideas.

THE SURPLUS OF DOCTORS.

A correspondent in one of the central states draws a faithful and painful picture of the profession in his locality. In a small town, which, with its neighboring population, will count about twenty-five hundred people, there are ten physicians all in active practice, or at least making desperate efforts to be active. Another physician, in Kansas, writes that in his village of less than a thousand inhabitants there are seven doctors. These are examples of what is found in very many localities. Almost everywhere practitioners are so numerous that it is simply impossible for them all to make the necessaries of life, if they have to depend on their profession alone. The consequence is that many cultivate some outside employment, or have to rely upon their private means.

All this is bad enough. Still graver is the fact that this condition of affairs shows no signs of improvement, but is yearly growing worse. With the multitude of half-cut medical colleges scattered through the land, the number of partially educated medical men is increasing. Already there are three times as many as can find profitable employment within the bounds of their avocation, and yet young men rush in constantly, with bright hopes doomed to certain disappointment.

Necessarily, there will result a general lowering of the professional standard, as the struggle for existence becomes more and more a hand-to-hand fight for the necessaries of life. We see the beginning of this in the growing desire to discard those principles of professional honor which nigh forty years ago were embodied in the Code of Ethics; we see it in the greater willingness of practitioners to affiliate with any class of pretenders, through whom they can obtain consulting practice and the like.

All the more does it become the duty of medical colleges, medical societies, and the nobler spirits of the profession, to set themselves firmly against these deteriorating influences.

Notes and Comments.

Partial Dislocation of the Head of the Radius Peculiar to Children.

Dr. Sydney H. Lindeman describes this condition in the *Brit. Med. Jour.*, December 5th:

It is a partial dislocation of the head of the radius, forwards on to the condyle of the humerus, perhaps in some cases reaching the shallow depression above the trochlear surface which goes by the name of the radial depression. It is generally caused by some one saving the child from falling by taking hold of the hand. In elder children, it is caused by nurses swinging them round by the hands, or it may result from a fall. In the first two cases, the tendon of the biceps largely participates in its production. This muscle acts both as a supinator and a flexor of the forearm; but it also flexes the arm on the forearm, when the latter is fixed, as in climbing; and, consequently, any great traction at the wrist causes it to be strongly brought into play, and so tends, by reason of its attachment to the posterior surface of the tuberosity of the radius, to bring the upper extremity of that bone forwards, out of its place.

After meeting with the accident, the child is brought evidently in great pain. The injured limb hangs down, midway between pronation and supination. The person who brings the child rarely knows where the injury lies; but generally thinks it is in the shoulder. Taking hold of the hand causes very great pain. The elbow is found to be hotter than its fellow, and there can always be felt an unnatural prominence on the outer side of the joint. Flexing the arm to a right angle and complete pronation can be accom-

plished; but, in attempting to flex more, or to supinate, some resistance is felt.

Reduction of the dislocation is accomplished by taking the hand of the child in the opposite one and strongly supinating, at the same time that the thumb of the other hand presses on the head of the radius. Before complete supination has taken place, a distinct "thud" will be heard, and the head of the radius felt to slip back. One of the peculiarities of these cases is, that the child, a few minutes after the reduction, will move the hand and arm, and will even grasp anything that may be offered to it, without apparently suffering any pain. These dislocations have a great tendency to recur, especially if not reduced early in the first instance. After the reduction, it is necessary for the joint to be kept at rest by a rectangular splint, the small tin ones being the most suitable for the purpose. The injury most frequently occurs in children of the strumous type, with large ends to the bones.

Quinsy and Rheumatism.

Apropos of the connection which has been sometimes claimed between these diseases, we reproduce the following case, which Dr. N. F. H. Fitzmaurice reports in the *Brit. Med. Jour.*, December 5:

"I was called, on November 7, to see Mrs. M., aged 60, married, and with family. I found her suffering from a severe attack of acute tonsillitis; her left side was chiefly affected, and she had pain in her left ear. This quickly yielded to treatment by tincture of aconite, fomentations, and brushing with astringent solution. The right tonsil then became implicated, and on the following morning the tongue was severely and acutely inflamed. The tongue was lanced, calomel was given, and the patient was nourished with enemata. The mouth was washed out frequently with eucalyptol in solution, and also lotion of chlorate of potash. In two days, the tongue and throat were quite well, but a peculiar huskiness of voice remained. The right shoulder now became very painful, and was found red and swollen; a liniment of soap and opium, with liquor epispasticus, was applied with benefit, and nourishment was given every two hours. A slight acid sweating was present; the pulse varied from 115 to 126; the temperature never rose above 100°, except on one occasion, when the thermometer registered 101°. The arthritis gradually improved in the shoulder, but attacked the sterno-clavicular joint and the corresponding end of the clavicle. The action of the heart gradually became feebler, and the patient quietly sank on the evening of November 14. For many years past she had been subject to slight pain in the right shoulder in the morning, disappearing during the day. Whether this acute attack was owing to the cause or causes which originated the quinsy, or whether the quinsy was the cause of the acute arthritis and glossitis, I am not prepared to say. The heart's sounds were normal; the lungs and kidneys were unaffected."

Lanolin, a New Ointment-Basis.

Dr. Oscar Liebreich read a paper on lanolin before the Berlin Medical Society, on October 28 (see the *Berliner Klin. Wochensch.*, No. 47). This substance is a mixture of cholesterin-fat (from keratin-holding tissues, such as sheep's wool in particular), and water. The pure cholesterin-fat stands, as Berthelot has said, between a resin and a fat, but is capable of taking up its bulk of water. It is perfectly neutral, and possesses properties which are not shared by the ordinary fats, nor by vaseline. In contrast with ordinary fats, lanolin with difficulty decomposes, and, which is its chief property therapeutically, it is extremely readily absorbed by the skin. It is in fact the natural fat of the skin, and of epidermic tissues generally, such as hair, hoofs of horses, feathers, etc., from all of which it has been obtained. As a proof of this high power of being absorbed, a five per cent. carbolic acid ointment, made up with lanolin, produced a feeling of numbness, without irritation, in the hand, in from one to two minutes after being rubbed in. The presence of cholesterin-fats is easily ascertained by Liebemann's cholestol test. The fat to be tested is dissolved in acetic anhydride (not glacial acetic acid). The solution gives a rose coloration, passing very quickly into dark blue and green when concentrated sulphuric acid is added. Glycerine fats do not give this reaction. The advantage of lanolin over vaselin and such paraffin derivates consists in its ready absorbability. Vaseline, as is well known, greatly hinders the absorption of therapeutical agents. It is an advantage to add five or ten per cent. of ordinary fat or of glycerine to lanolin, so that the unctuous character may be better preserved.

Gastrostomy in a Boy, aged Four.

Before a recent meeting of the Clinical Society of London, Mr. John H. Morgan described this case:

The patient, on March 1st, swallowed some caustic alkali. The mouth and fauces were burnt at the time, and he vomited phlegm for some weeks following. No solid food could be swallowed for fourteen days. Ten weeks later, he was admitted into the Hospital for Sick Children under the care of Dr. Cheadle, in a poorly nourished and pallid state. He could then swallow only very small quantities of fluid with difficulty, often followed by vomiting of muco-purulent matter. Though given nutrient enemata from the first, the emaciation increased, and an attempt to pass a catheter down the œsophagus was unsuccessful. For a few days the powers of swallowing improved; but this was only temporary, and the emaciation became so extreme that, after failing to pass a catheter under chloroform, the operation of gastrostomy was performed on August 17th. The stomach was secured with thirteen sutures, and was not opened until thirty-one hours later; when this was done, on account of the very feeble condition into which the patient had sunk, some beef-tea and brandy were immediately introduced through an empyema-tube. Nourishment was administered every two hours, and, on the fourth day, he passed a healthy motion. He remained feeble and irritable for the first seven days, at the end of which time he showed a decided improvement; but it was not until three weeks had passed that he began to increase in weight. He had continued to gain weight and strength, and now looked well nourished, and weighed the same as at the time of his admission. No attempt had been yet made to dilate the œsophageal stricture, but colored fluid had passed from the mouth into the stomach.

The Effect of Double Ovariotomy on Menstruation.

At a recent meeting of the Société de Chirurgie, M. Terrier read some clinical notes on the influence of double ovariotomy on menstruation. He has performed the operation twenty-two times. In some of his patients he has been able to study their condition during ten years after the operation; in others, during one year only. One patient had menstruated from the age of 16 to the age of 22; she was aged 52 when operated on. Two others, whose general state of health was very serious, had not menstruated for several months. All the others, thirteen out of twenty-two, menstruated regularly. The two ovaries were removed, and, in most of the patients, the menstrual flow took place. In one case of single ovariotomy, the menses reappeared three months after the operation, and were regularly repeated until the remaining ovary was removed, and then they disappeared. In another instance, in which the right ovary was removed, the menses continued; the left ovary was subsequently removed, and, during five months afterwards, the menstrual flow took place regularly at the normal periods; later on, the menopause was definitely established. Three patients menstruated regularly during seven years after undergoing double ovariotomy. M. Terrier concludes that double ovariotomy is generally followed by suppression of the menstrual flow. This may not occur immediately; sometimes the menses appear once after the operation, sometimes twice during the following year, sometimes four times during the three subsequent years.

Syphilitic Hemiplegia.

To the Harveian Society of London, Dr. Sidney Phillips exhibited a man aged 37, who had contracted syphilis seven years ago, and who, in addition to occasional headache, had had three epileptiform seizures within the last twelve months. In August last the right third nerve became paralyzed, and a few days later also the right limb and the right facial muscles. Iodide of potassium in doses of twenty-five grains, in combination with one-drachm doses of solution of perchloride of mercury, cured the patient of his hemiplegia, but produced only a very slight improvement of the ptosis. Whilst under treatment, the patient had two attacks of painless conjunctivitis of the right eye, which temporarily aggravated the ptosis. Dr. Phillips considered that in this case the lesion was double, the hemiplegia being due to disease in the left side of the brain, whilst the right third nerve was implicated at the base of the skull. The conjunctivitis was probably due to pressure on the ophthalmic vein.

Stammering of the Urinary Organs.

Difficult urination, wherein no pathological change can be found, where the patient has a difficulty in passing water at certain times and places, while at other times and under other circumstances no such trouble is experienced, is what Sir James Paget calls stammering of the urinary organs. Dr. J. Henry C. Simes describes two cases in the *Polyclinic* (January 15), in both of which there was a variety of impotency, in which there was desire, imperfect or temporary

erection, and premature ejaculation of semen. The treatment consists in tonics, quieting the patient's anxiety, and convincing him that it is not necessary always to accomplish micturition when the attempt is made, which idea causes him so to strain that in one case it caused hernia. If the cause can be discovered, as the presence of a second party, it should be removed; regular habits should be encouraged, and the catheter can be freely used.

Correspondence.

The Epidemic in Farmland, Ind.

Eds. Med. and Surg. Reporter:—

For the account of an apparently similar epidemic to that spoken of by Drs. Myers, of West Virginia, and Geyer, of Ohio, I would respectfully refer those interested to the issues of the Cincinnati *Lancet and Clinic* of February 14 and May 9, 1885, where they will find the report of numerous cases of a "Peculiar Epidemic at Farmland, Ind." Its prevalence concerns me no less at the present date than it did at the above, for the diagnosis is yet problematical, and the disease still exists.

The prognosis differs widely in different cases, the gravity depending more upon the complications than the disease *per se*.

I cannot consent, however, that our epidemic is an hybrid of malaria and typhoid. We have no uncomplicated cases of malaria in this locality, and it would be highly unreasonable to suppose that it complicated other diseases. Besides, I would be far from contributing my mite toward resuscitating that confusing and ill-conceived term, typho-malaria. Typical cases of our epidemic have also been reported to our local societies, with the view of eliciting information, but with negative results. The following will very well serve to illustrate the disease in consideration:

Mrs. E. F. H., married, of delicate physical structure, and slightly deteriorated mental faculties, was attacked, after two or three days of trifling indisposition, October 31, 1885; pain in the bowels being the chief if not the sole complaint, in all respects like the ordinary colic of indigestion.

When seen, she was restless, and writhing in pain; the conjunctiva markedly yellow and congested; tongue covered with a dark yellow coat; breath fetid; pulse soft and rather weak, 84 to the minute; respirations 24, and shallow. Complains of chilly sensations; temperature 100°.

Brain, as evinced by the mental faculties, denotes probable softening as the result of clot. This conclusion was also warranted by the presence of quite noticeable hemiplegia. Bowels costive, abdominal walls rigid, and much tenderness over the liver, but still more in the right iliac region. A hypodermic injection of morphia and atropine was administered, and a laxative ordered, and much hope was entertained that the patient might report better the next day. Our expectations, however, were not realized; for the symptoms not only continued, but were aggravated. The temperature reached 102°, bowels not yet moved, nausea and vomiting of bilious matter; pain now located at the head of the colon and extending down the right groin, with induration and enlargement of the lymphatics in this region.

Three days later found the temperature normal, or slightly subnormal, and the bowels not yet moved. Pain and tumor in the right iliac region, also nausea; but little nourishment being retained in the stomach; thirst intense, and a sweetish, sickening odor emitted by the breath. The vomit, at times, has a fecal odor and appearance. The retracted abdominal walls have given place to tympanites; singultus became troublesome, breathing shallow, hurried, and attended with dyspnœa. All indications of mechanical obstruction of the bowels and impending collapse were present.

About the eighth day, however, the bowels were moved—the first discharges consisting of putty-like scybala, which later assumed a bilious character, with a large amount of mucus, copious, however, and attended with considerable tormina. The diarrhœa continued to the end of life. The periodical pains which prevailed in the right iliac region from the inception of the disease, continued throughout the diarrhœal stage; also, the iliac enlargement and tenderness. Death occurred on the eighteenth day, as the result of the unyielding colliquative diarrhœa; the local inflammation being at no time very intense, and the fever the greater part of the time *nil*. Had it not been for the antecedent ill-health of the patient, she would, doubtless, have recovered.

Other cases are much less severe; the febrile and abdominal symptoms subsiding in from five to ten days, leaving the patient to recover slowly. Relapses and complications are not uncommon. Diffuse peritonitis, from extension of the iliac inflammation, has resulted more than once under my observation

in adults. Inflammation of the middle ear and cerebral involvement are occasional sequelæ in infants.

The breathing is often shallow, and attended with sighing and yawning; sometimes a roseolous rash appears on the face and chest; delirium is not a prominent feature, unless the brain becomes involved, but dizziness is quite common. The cases commence, and may remain, very like catarrhal jaundice, but many are attended by veritable typhlitis or perityphlitis, which adds greatly to the danger. The cæcal complication is confined to those cases in which the bowels, for the first few days, are costive, and this is a class of the cases which is protracted, hard to manage, and even dangerous. It affects all ages, and yet does not seem to be highly contagious, if so at all.

In the diagnosis, malaria can be excluded at the threshold, because it has not the semblance of malaria. And allow me to say here, that while I have no prejudice against the terms, I do think that malaria and typhomalaria constitute the bane of modern medicine, especially in the west. Pity it is that the latter was ever coined, and the former is equally as good an apology for ignorance as *biliousness* was fifteen years ago.

The proper conception of our epidemic might place it within the limits of bilious typhoid, typhus, or relapsing fever—the likelihood to each existing in the order mentioned.

I might report many other cases, or give the symptoms more in detail, but for these the reader is referred to the journals mentioned. L. N. Davis, M. D.

Farmland, Ind., Jan. 26, 1886.

News and Miscellany.

Medical Society of the State of New York.

The eightieth annual meeting was held in Albany, February 2, 3, and 4.

The President, Dr. A. Vander Veer, of Albany, recommended that the number of delegates and permanent members from the county societies be increased fourfold, and suggested that the meeting be held each alternate year at some other place than Albany, the time and place to be left with the Nominating Committee. He hoped the circular sent out by Dr. A. Jacobi, of the Committee on the Collective Investigation of Disease, appointed at the International Medical Congress at Copenhagen, would receive due consideration. Disapproval was expressed of the action of the meeting of the American Medical Association at New Orleans concerning the Congress at Washington in 1887. He trusted the Society would support the Committee on Legislation, and that we might have a law at least as effective as those of several other States regarding admission to the practice of medicine.

ABSCESS OF THE KIDNEY.

Dr. C. L. Stiles, of Owego, reported a case occurring in a man fifty-seven years of age, the result of traumatism, and in which there was very notable increase in the size of the tumor in twelve hours, without rigor or pain, attended by a small amount of pain and general disturbance during the illness, and accompanied by a sudden discharge into the bladder.

THE CURATIVE POTENCY OF PROLONGED SLEEP.

Dr. J. Leonard Corning read a paper on this subject in which he said the essential features of a scheme of brain rest are:

1. Progressively prolonged sleep.
2. Increased general and cerebral nutrition.
3. Diminution of psychical irritation.
4. Elimination of sensory impressions, particularly those of light and sound.

In carrying out this scheme of treatment, Dr. Corning is in the habit of secluding the subject in a darkened room, eventually for from ten to fifteen hours at a time, according to the amount of sleep which it is desired shall be had during the twenty-four hours. The amount of sleep is *progressively* increased by habit, moderate medication, and hydrotherapy; but he never resorts to forced sleep by the reckless abuse of sedatives. When the patient awakes, as is sometimes the case, two or three times during the hours set apart for rest, nourishment is administered, but always in an easily digested form. The few hours of wakefulness are devoted to some form of amusement, but all forms of mental exertion are strictly prohibited.

A CASE OF EMPYEMA.

Dr. B. F. Sherman, of Ogdensburg, reported a case of acute empyema treated by making an opening into the pleural cavity in front and another behind the scapula, and washing out the cavity with an antiseptic solution, the entrance of air being prevented. The patient made a satisfactory recovery, and when he was last examined no difference could be detected between the two sides of the chest.

PULMONARY CAPACITY.

Dr. W. S. Ely, of Rochester, read a paper

in which he spoke of natural and acquired defective chest expansion, and advanced the view that lung expansion can be relatively increased by a series of exercises which may be called pulmonary gymnastics; this can be accomplished by bringing into special exercise the auxiliary respiratory muscles. He believed that the subject was of sufficient importance to secure the attention of medical men, to whom such cases should be referred exclusively for the instructions proper to be observed in each case. The mode of management is not applicable to acute cases.

THE TREATMENT OF AURAL POLYPI BY THE INJECTION OF CARBOLIC ACID.

Dr. Bendell, of Albany, regards this as a more satisfactory method than either operative procedures or the use of caustics and astringents.

Dr. Thomas R. Pooley, of New York, objected to carbolic acid because of the possible occurrence of pyæmia or septicæmia, and the difficulty of limiting the sloughing. He employs avulsion, and said that the hemorrhage attending this operation in his experience had been insignificant.

Dr. Sherman, of Ogdensburg, had used tannic acid in these cases with good results.

Dr. W. F. Mittendorf, of New York, said that the plan of injecting with carbolic acid originated with him about the year 1881, but he limited its use to cases in which the growth presented at the external meatus. The operation, however, had proved so painful that he had abandoned it entirely, and now resorts to the use of the snare.

Dr. O. D. Pomeroy, of New York, said that injection of aural polypi was destructive, painful, and also unnecessary, as there were other and better means for their removal. He uses the forceps, and cauterizes the base with nitrate of silver.

RESULTS OF THE OPERATION FOR CONVERGENT SQUINT.

Dr. D. B. St. John Roosa read a paper on this subject, in which he stated his belief that the operation is permanently successful, if properly understood. There is, however, a division of sentiment on this question. The most favorable time for operation is between five and seven years of age, and vision can be rendered clearer by the use of glasses in a large proportion of cases. There is never any substantial improvement of the vision of the squinting eye by the operation for squint; the improvement in vision is not due to the operation, except in so far as it places the patient in a condition to wear glasses. The operation may successfully remove the deformity in seventy or eighty per cent. of the cases of convergent squint, and this percentage may be raised to ninety-five per cent.

NON-UNION OF FRACTURES, TOGETHER WITH A CONSIDERATION OF SOME MODERN METHODS OF TREATMENT.

Dr. George R. Fowler's (Brooklyn) paper may be thus summarized:

1. In all cases of simple delayed union, the percussion method of Thomas, combined with an efficient retention apparatus, will be found to offer the readiest and most efficient means of bringing about union, provided this does not depend upon some dyscrasia. In cases of fibrous union, benefit may also be expected from this plan, provided absorption and attenuation of the ends of fragments, or eburnation, have not taken place.

2. Brainard's method of drilling the fragments, and this failing, freshening the ends of the bones and uniting the periosteum by either the method of Jurdain or Rydygier, combined or otherwise, according to the exigencies of the case, with wire suture of the ends of the fragments, should take the place of the old Dieffenbach operation. This should be done with a modified antiseptic procedure, and is applicable in cases in which the percussion method of Thomas has failed because of delay in instituting early treatment, and in pseudarthrosis.

3. Cases in which it is found impossible, because of excessive loss of bone substance, to unite the periosteum by sutures or to wire together the ends of the bones, should be treated by bone transplantation, under antiseptic precautions, either by the method of MacEwen, or that of von Nussbaum.

RHEUMATIC AFFECTIONS OF THE JOINTS.

Dr. A. Hadden, of New York, claimed that rheumatoid osteo-arthritis, often called rheumatic gout, is a disease distinct from either rheumatism or gout, and that the pathological changes are in the osseous structure of the joints. He held that the disease attacks persons who live chiefly on amylaceous and saccharine foods; and he stated that a similar disease, called "bone spavin," attacks the horse and other graminivorous beasts, while in all carnivorous animals and in birds no such disease is known. In the treatment of this disease, therefore, he recommended the substitution of nitrogenous for amylaceous and saccharine foods, and by this method he has obtained, clinically, the best results.

SPONTANEOUS EXPULSION OF A LARGE CALCULUS IN THE CASE OF A FEMALE, AGED SIXTY-EIGHT YEARS.

Dr. Harvey Jewett, of Canandaigua, presented the calculus. The woman had suffered for several years from bladder symptoms. The stone had rough edges. Subsequently Dr. Jewett extracted another stone, which weighed six and a half drachms. Gravel ceased to pass after the patient began drinking lithia water.

INFANT FEEDING.

Dr. E. F. Brush, of Mount Vernon, read a paper with this title, and pointed out some simple methods of feeding an infant when it had been deprived of the breast. He urged the value of simple foods, in preference to the so-called "patent foods," the composition of which was often unknown. He had examined the composition of the once famous "Liebig's food for infants," and of another popular food, and indicated the dangerous amount of alkali contained in them, citing Dr. Jacobi's warning that "we are not very careful in doses of alkalies in general," and Dr. Stillé's remark that alkaline treatment "lessens the amount of fibrin in the blood." He showed, by the figures furnished by one of the advocates of peptonized food, that the results of such feeding were not satisfactory. Proceeding, then, to the immediate subject of his paper, he stated that one of the greatest elements of failure in the artificial feeding of infants was the desire to give one sort of food alone under all circumstances, and hence the blind prescription of patent foods. He advised, on the contrary, the preparation of foods from simple articles to meet the requirements of each case as it arose. When with food thus prepared there was a failure, the physician, at least, knew what the failure arose from. Commencing, then, with the child at birth, the author gave his formula for the best substitute for colostrum, and his further treatment if the cathartic effect was either excessive or defective. He then discussed the question of the best staple food. He had no hesitation in saying that it was cow's milk, which, however, was subject to many conditions that rendered it unfit, unless due care was exercised. In 1879 he had pointed out the difference between the milk of the ruminant and non-ruminant animals as regarded particularly the quantity and quality of the casein contained in them, and the difficulty experienced by infants in digesting a milk intended for calves. When an infant vomited a hard curd, the indications were that the milk must either be prevented from coagulating in the stomach, or coagulated and broken up before entering the stomach. He showed that it was inadvisable to use an alkali, and therefore preferred the latter course—that of coagulating and breaking up the milk before giving it. In other cases he recommended the addition of lime-water as the safest agent, as it did not, like other alkalies, keep the stomach in an alkaline condition, nor cause an acid condition of the intestines. In case of diarrhœa in children fed on milk, the indications were to stop the milk immediately. The milk was usually the cause of the trouble, and it was rendered unfit by the physical condition of the cow, such as rutting, gestation, the ingestion of poisonous herbs, cruel treatment, and the like, to all of which states many cases of diarrhœa in infants could be traced. In these cases of diarrhœa he recommended oatmeal-water, which his analysis had convinced him was somewhat similar to milk in composition. He insisted on the necessity of the medical attendant himself preparing or teaching the preparation of these simple foods. In all cases the child should be put back on its ordinary milk diet as soon as possible. As to the kind of cow best adapted to supply milk, he preferred the common-grade cow to the Jersey or fancy breeds. The latter were of a tuberculous tendency, the fat in the milk was not sufficiently emulsified, and they were of an excessively nervous temperament, while the common cow ordinarily was gentler and a good feeder. She should always be stall-fed. When milk was bought, that of one cow should always be avoided. In cases of constipation, raw malt-water, carefully prepared as a diluent of the milk, was efficacious.

PAPAIN OR PAPAYOTIN.

Dr. Jacobi read a paper on this subject. After referring to the chemistry of this substance, which is obtained by adding alcohol to the juice of the papaw plant, the physiological action was described. Its therapeutic effects were next considered. It has been found innocuous when taken internally; but when injected subcutaneously, it is followed by dangerous symptoms of paralysis of the heart and nervous system. Its effect has been compared to that of pepsin and pancreatin, with this exception, that it is effective in smaller doses. It is useful in alimentation.

Diphtheritic membranes are dissolved by it in a few hours. Several cases of diphtheritic deposit were described as showing the effects of this drug, one part to four of water

and four of glycerine. In these cases the membrane was softened and dissolved, and disappeared within forty-eight hours. He exhibited specimens of egg, meat, and cheese digested by a solution of papayotin of the strength of 1 to 250.

GENERAL ARTERO-CAPILLARY FIBROSIS.

Dr. Alfred L. Loomis discussed its relation to cardiac and renal disease. He regards it as a general condition which involves the vascular system, and manifests itself in a variety of morbid changes in different parts of the body. The effect of the fibroid degeneration is to diminish the calibre of the arterioles. It is to be recognized by the character of the pulse, it giving evidence of increased arterial tension. The relation which left cardiac hypertrophy has to the small kidney was discussed at length, and the relation which both morbid conditions sustain to a general fibroid condition of the arteries and arterioles was demonstrated.

ULCERATIVE ENDOCARDITIS.

Dr. H. R. Hopkins discussed the question of its primary occurrence, its symptomatology, and its etiology. Whether primary or not is questionable. In the vast majority of cases it is secondary, especially to scarlet fever, pneumonia, and pyæmia. He thought one should be guarded with reference to expressing an opinion concerning the etiological relation existing between the disease and micro-organisms, although the relation of cause and effect was maintained by many observers.

THE EARLY MANAGEMENT OF CASES OF MENTAL DEPRESSION.

Dr. Willis E. Ford thought that in the majority of cases a period of depression precedes the development of insanity, and that many cases of grave insanity might be prevented by proper treatment. The cases may be divided into two classes: those in which there is intellectual perversion, and those in which the emotions are alone disturbed, and there is no fixed delusion. In cases where the physician cannot secure the confidence of the patient, where there is a suicidal tendency requiring constant watching, and where careful attention cannot be had at home, the patient had better be removed to an asylum. Cases of mental depression, where the emotions are alone affected, where there are no delusions, are improved by diversion and by travel, and appropriate medical treatment. In some cases of sudden onset of melancholia, treatment by sedatives has been effective.

HINTS ON THE TREATMENT OF DIPHTHERIA.

Dr. J. M. Bigelow read a paper on this subject in which he advocated the use of tincture of chloride of iron in fifteen-drop doses with glycerine and water, muriate of pilocarpin in one-twentieth of a grain doses every two hours, and twenty minutes later two or three tablespoonfuls of whisky—the mouth to be cleansed with a two per cent. solution of carbolic acid, and a spray of lactic acid to be also employed. This treatment has been followed by satisfactory results in his practice.

TRANSPLANTATION OF THE EYEBALL.

Dr. Lucien Howe made a communication on this subject, and exhibited the rabbit upon which he had performed the operation three days ago. The cornea was comparatively clear, and the iris was visible, and there was only slight conjunctival inflammation. But the cornea always sloughs, and the globe also, but the operation shows that a slight amount of circulation is established in the globe.

THE RADICAL TREATMENT OF HYDROCELE AND VARICOCELE.

Dr. E. L. Keyes read a paper in which he recommended subcutaneous ligation of the veins in varicocele with carbolized catgut, which in his hands has uniformly been successful. Etherization is not admissible, because the patient must stand up, and he has used both straight and curved needles.

For hydrocele he uses pure carbolic acid by injection, suggested by Dr. Levis, of Philadelphia, with a glass syringe having an ordinary hypodermic point; first withdrawing the fluid, and then throwing in pure carbolic acid deliquesced with a few drops of glycerine—one drachm.

Dr. Weir, of New York, spoke of the caution necessary in the use of more than one drachm of the acid for a single injection in hydrocele. He had used the subcutaneous ligation for varicocele in twenty-two cases, with six unsatisfactory results. For small varicocele this method is the best; but for the large he truncates the scrotum, and ties the veins in one or two places.

Dr. Gerster, of New York, added his testimony to Dr. Weir's in the treatment of small varicocele, but for the large he favored complete exposure of the parts to be operated upon under antiseptic precautions.

Dr. Pease, of Syracuse, saw no reason why Dr. Keyes's method was not as applicable to large as to small varicocele.

ACUTE NEPHRITIS, ESPECIALLY AS FOLLOWING DIPHTHERIA.

Dr. A. R. Simmons, of Utica, presented a paper on this subject. In diphtheria, he said nephritis results from the products of the disease within the first eight days. Irritant remedies are to be avoided; mercury must be used with care. The indications for the treatment are to relieve congestion of the Malpighian tufts, to reduce the thickened mucous membrane, and to carry off the epithelial debris. Two general plans of treatment may be pursued: one to increase the excretory action of the kidneys; the other to act on the other excretory organs, viz., bowels and skin. A combination of these methods is the best plan. Irritant diuretics and nitrogenous food should be avoided. He concluded his paper with a series of illustrative cases.

THE MANAGEMENT OF CLUB-FOOT.

Dr. V. P. Gibney, of New York, read a paper on this subject, in which he considered the abuse of tenotomy, the advantages of early treatment, how the mother may intelligently co-operate with the medical attendant, the delusion of "rapid cure," the value of plaster-of-Paris as an adjuvant, and also the extensive surgical operations sometimes adopted.

REMOVAL OF A PIECE OF IRON FROM THE EYE BY A COUNTER OPENING.

Dr. Mittendorf read the history of a case in which a piece of iron had entered deep into the eye, and he removed it through a counter-opening made near the cornea. The case did comparatively well, although it occurred before much was known about antiseptic eye surgery.

Dr. Roosa thought it was important to bear in mind that the presence of the foreign body in the eye was not the only danger; it might be removed, and the wound caused by its entrance would still be a source of danger. Of course, the presence of the foreign body was an additional source of danger, and it should be removed if practicable.

Dr. H. D. Noyes, of New York, briefly related three or four cases in which he had removed or attempted to remove pieces of iron from the eye. In one case an unsuccessful attempt had been made by a colleague soon after the accident. The speaker thought the softening of the tissues about the foreign body, which had probably taken place since the accident, might enable him to use the magnet successfully. An incision was made, and, the electro-magnet being used, the piece of metal was withdrawn. In another case, the patient had consulted Dr. Mittendorf some years before for a piece of iron which had entered the eye. It was not removed, but the patient lost sight in the eye. Subsequently a second piece of iron entered the same eye, and the speaker, when prepared to enucleate the eye, tried the magnet, thinking that if he could remove both pieces of iron, he would leave the ball. He succeeded in withdrawing only one piece with the magnet, enucleated the eye, and afterward found the other piece imbedded in the retina.

NON-VENEREAL SYPHILIS.

Dr. L. D. Bulkley, of New York, read a paper in which he drew the following conclusions:

1. Syphilis was not necessarily a venereal disease, but in a considerable proportion of cases acquired quite unconsciously and in an entirely unexpected manner.

2. Failure to obtain a venereal history should not lead to the conclusion that certain lesions were not those of syphilis.

3. The syphilitic virus could be carried a long distance, and, after some time had passed, be able to cause syphilis in the inoculated.

4. Non-venereal chancres had been mistaken for epithelioma, and operations for removal had even been performed.

5. Non-venereal syphilis often showed great malignancy.

MEDICAL TESTIMONY AND THE HYPOTHETICAL QUESTION.

Dr. C. Wey, of Elmira, read a paper on this subject, in which he deprecated the present condition of expert testimony. One expert is contradicted by another equally competent expert. The charge that medical experts are hired advocates is capable of proof. The opinions of scientific physicians are often offset by those of local physicians of less attainment. Physicians and lawyers agree that the present system should be abandoned. Dr. Wey favored the selection of an expert or board of experts by the court or by the Governor.

A hypothetical question, he said, may be based upon acts which are entirely separated from their surroundings, giving them entirely different significance, and based upon exceptional conditions of the individual. Every one's conduct is at periods open to the danger of hypothetical questions.

Dr. B. F. Sherman said that this is a question of great importance, and one which is neglected by the profession. The expert

should be free from the bias of being employed by one or other party. He should be the witness of the court. In many questions scientific evidence is stronger than that of supposed eye-witnesses. While what Dr. Wey says is true with reference to hypothetical questions, yet the opposing counsel have an opportunity to correct any misrepresentations which may be made.

ANTISEPTICS IN MIDWIFERY.

Dr. Walter B. Chase, of Brooklyn, read a paper in which he held that vaginal injections during the progress of labor are harmful, by washing away the mucus which coats the vagina, thus retarding labor and increasing the danger of laceration of the cervix. Subsequent to labor the injection is not required and may unnecessarily irritate the patient, and may even enter the uterus and the peritoneal cavity. Pyæmia and septicæmia do occur sometimes where injections are not used, but that they are the result of their omission is not proved. The conditions under which antiseptics are to be used were then stated. The pregnant woman is to avoid all contagious diseases. If exposed to them, she should immediately change her clothing and bathe herself with an antiseptic solution. The physician, if exposed, should act in the same way. Instruments are to be treated with antiseptic solutions. Antiseptic injections should not be used in normal labor until its termination. In complicated cases, maceration of the fœtus, etc., their use may be indicated. In cases of retained placenta, laceration of the cervix or perineum, injections may be required.

THE LIMITATION OF THE CONTAGIOUS PERIOD OF SYPHILIS IN RELATION TO MARRIAGE, ETC.

Dr. F. N. Otis, of New York, read a paper on this subject. According to the views entertained by the author of the paper there is no such thing, strictly speaking, as hereditary transmission of syphilis; that there is no well-authenticated evidence of communication of syphilis after the secondary stage has been completely passed; that after the absence of all symptoms referable to syphilis for one year, marriage can be entered into with safety; that communication of syphilis after the third year of its existence is rare; that tertiary syphilis is due to obstructive changes affecting the lymph-channels, caused by the disease in its secondary stage; that spontaneous recovery from tertiary syphilis may occur, etc.

TREATMENT OF TERTIARY SYPHILIS OF THE NOSE, MOUTH, AND THROAT.

Dr. D. H. Goodwillie, of New York, read a paper, in which he held that diet and hygiene are to be carefully regulated. While mercury is valuable in the early stage, it is not useful in the treatment of the sequelæ. Iodide of potassium is beneficial if properly employed, but if pushed too far it may be injurious. For the removal of diseased bones, he uses a revolving burr. He presented a number of drawings and models of cases operated upon, and exhibited an electro-motor and storage battery for operating the burr.

HYGIENE OF THE EAR.

Dr. C. R. Agnew gave a synopsis of his paper, in which he had collected 2,844 cases of consecutive diseases of the ear, and of which 2,183 were of the middle ear, 6 of the auricle, 362 of the auditory canal, 15 of the mastoid alone, 244 of the labyrinth, and 34 unclassified. The important etiological factor in the middle-ear cases was naso-pharyngeal disease.

LEPROSY IN JAPAN.

Dr. D. B. Simmons, of Poughkeepsie, read a paper in which he said that the disease is confined to no class, and affects both the rich and poor. Those with light complexion, blushing easily, appear most likely be affected. In the children of those affected, a light color of the retina has been noted; and in confirmed cases there is hypertrophy of the right heart. The disease is regarded by the people of Japan as essentially hereditary. He earnestly opposed the idea of infection.

Dr. Bell thought that in Minnesota and Wisconsin, where Norwegian colonists have settled, there should be sanitary regulations enacted to prevent the intermarriage of persons in whom this disease is hereditary, and thus to prevent its appearance in this country.

THE TREATMENT OF HEMORRHOIDS IN PREGNANCY.

Dr. William H. Bailey, of Albany, read a paper in which he referred to the frequency of the condition and the absence of reference to it in the text-books. In reference to its treatment before confinement, he advised regulation of the bowels with a pill of aloes, hyoscyamus, and ipecac; after confinement, with a mixture of sulphate of magnesia, carbonate of magnesia, and sulphur. In cases in which the hemorrhoids are pressed out, he uses warm fomentations.

Dr. Ely recommended, in those cases in which the hemorrhoids tend to protrude, the use of a rubber bandage passing between the thighs and secured to a muslin bandage

passed around the waist. This may also be used in males.

THE EMISSION OF SEMEN AS A MEANS OF DIAGNOSIS OF DEATH BY HANGING.

Dr. Francis M. Hamlin, of Auburn, read a paper in which he held that this is more constantly present than is generally supposed, and that when there is no external appearance of semen, pressure upon the urethra will cause its appearance. He thought it possible that this may occur in cases of sudden death from other causes; but to establish this point further observations are required. He recommended the following method for discovering seminal stains on cotton cloth: Put two drops of water on a glass slide, and then lay on the water a small piece of the muslin containing the supposed stain; fray out the ends and let it remain for five minutes; then examine the slide under the microscope. If the stain be on woolen cloth, shave off a portion of the stain, and treat the specimen thus obtained in the same way.

OFFICERS FOR THE ENSUING YEAR:

President—W. S. Ely, M. D., of Rochester.

Vice-President—Solomon Van Etten, M. D., of Port Jervis.

Secretary—Wm. Manlius Smith, M. D., of Syracuse.

Treasurer—Charles H. Porter, M. D., of Albany.

Time and place of next meeting, Albany, first Tuesday in February, 1887.

Personal.

—Dr. William B. Atkinson has been appointed Special Inspector for the Delaware District by the State Board of Health of Pennsylvania.

Items.

—Prof. Bartholow recommends for superficial neuralgia, that a 5 to 20 per cent. ethereal solution of menthol be painted over the part.

—Dr. W. Switz reports four cases of lupus successfully treated by lactic acid. It produces very little pain. The healthy tissue may be protected by smearing with ointment.

—They have "vaccination bees" in Maine. A young lady gives a party and has a surgeon present who vaccinates all the guests "for the fun of the thing," at the hostess's expense.

—The St. Petersburg medical papers state that in a convent at Lebedin, in the Kharkov government, Russia, there are now living two nuns whose ages are known, on reliable authority, to be 100 and 112.

—The Moscow popular medical journal, *Doktor*, will next year change its name to *Novosti Terapii* (Novelties in Therapeutics), snd will deal with the progress of therapeutical science, and with the literature of the aubject.

—In speaking of anæsthesia by the rectal administration of the vapor of ether, the *British Medical Journal* concludes that this method is not likely to come into general use, though it may be useful in operating on the face or in the mouth.

—"I am just as much opposed to intemperance as anybody," said Smith, "but, nevertheless, liquor rightly used is a blessing to humanity. When I was ill last year, I really believe it *saved my life*." "Very likely," said Brown, "but how does that prove that liquor is a *blessing to humanity?*"

—Lieutenant Greeley has recently returned to Washington. His health is greatly improved, and he is now quite robust, although still suffering somewhat from his back. He greatly enjoyed his stay in Great Britain, and is enthusiastic regarding the treatment he received there. Wherever he went, he was heartily welcomed.

—The first regularly organized asylum for the care and treatment of inebriates in Sweden has lately been opened at Bie, under the care of Dr. Levin. The prospectus is emphatic on the question of disease, and announces that it is to be an asylum for dipsomaniacs and the insane drunkard, and not a place for the religious treatment of physical disorders.

—A writer in the *Bibliotheca Sacra* for October says that $125,000,000 were spent for opium in China in 1884; that over fifty millions of persons were computed to be using this drug, and that the mortality was not less than six hundred thousand a year. Seven thousand tons of opium were sent from India to China last year. This does not include the amount raised at home.

—M. Terrillon recently removed from a man, thirty-five years of age, a lipoma weighing fifty-five pounds. It was attached to the mesentery, and the incision necessary for its removal extended from the pubis a distance of twenty-two inches, nearly to the xyphoid appendix. Eight days after the operation, the patient was reported to be in good condition, with every chance for a perfect recovery.

ENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle, pleasantly flavored. Retail $1.00. All of it pure pepsin.
See page 10.

WHOLE No. 1512.] FEBRUARY 20, 1886. [VOL. LIV., No. 8.

PRICE $5.00 PER YEAR. SINGLE NUMBERS 10 CENTS. ESTABLISHED 1853, BY S. W. BUTLER, M. D

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin,*" must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also anrmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

TETANUS.

BY N. SENN, M. D., MILWAUKEE, WIS.,

Professor of the Principles and Practice of Surgery and Clinical Surgery.

(*Concluded from page* 197.)

The last disease which it might be mistaken for is hydrophobia. The muscular spasms in hydrophobia are more of a clonic character, and remain limited to the muscles of deglutition and respiration. In the prognosis you must be guided, in the first place, by the extent of the central lesion, as evidenced by the number of muscular groups affected. If the central irritation is circumscribed, only a limited number of muscular groups are affected, and when this is the case, we are usually dealing with a mild form of the disease. If, on the other hand, in the early history of the disease there is rigidity of an extensive muscular area, the disease is a grave one; and more particularly if at the same time, as will likely be the case, there is a high temperature. Time is one of your most important elements in rendering a prognosis. Hippocrates always considered the prognosis dubious the first four days. Severe cases may terminate fatally from the second to the sixth day, usually, so that time gained after the sixth day, with the symptoms remaining stationary, the prognosis becomes more favorable as time increases. In the mild cases of tetanus, terminating in recovery, it may take weeks and sometimes months before all muscular rigidity has disappeared. I have observed several severe and acute cases where within forty-eight hours after the commencement of the first symptoms, death occurred; but after the sixth day, with symptoms remaining stationary, the surgeon's hope increases as time elapses.

Another important point is the probable cause of the disease. If the injury has been slight, infection limited, the disease assuming a mild type, your prognosis may be favorable; but should the symptoms develop themselves incidental to injuries grave in themselves, the prognosis becomes correspondingly serious, so that in tetanus attending severe lesions, followed by traumatic infection of other types, attended, perhaps, by septicæmia or pyæmia, our prognosis always must be unfavorable; in other words, if there is no possibility of removing the primary cause or source of infection or irritation, the prognosis increases in gravity.

Like in all other forms of wound infective diseases, the prophylactic treatment is the most important. Practically, it is important to recognize the microbic origin, and institute early and efficient treatment in accordance with this supposition. I therefore, again, emphasize the necessity of adopting aseptic measures in the treatment of wounds, with a view not only of preventing suppuration, but also other forms of infection. There can be no question but that since the introduction of antiseptic surgery tetanus has been uncommon. The clinical fact is patent that it is prone to follow injuries where a foreign body has remained in the wound, and where subsequently from this cause there is greater danger of infection on the one hand, and peripheral irritation on the other; this is especially true of injuries about the hand. It is therefore of paramount importance to treat slight injuries of

the hand, and more especially 4th of July injuries, which so frequently end in tetanus, with the greatest care. No matter how trifling the injury may be, disregard in this direction has only too often been followed by the most serious consequences. A small wound of the hand when neglected may serve as an avenue for the ingress of germs, which according to their action may destroy life in a variety of ways. If necessary, enlarge the wound, search carefully for foreign bodies, if there is reason to believe that they are present; take plenty of time to secure an aseptic condition for the wound, and conduct the subsequent treatment on strictly antiseptic principles. If suppuration should take place, be sure to secure efficient drainage, and resort to frequent antiseptic irrigations. By following these directions you will not only have the satisfaction of securing the most favorable condition for the healing of the wound, but you will have, at the same time, carried out the most efficient prophylactic treatment against tetanus.

In the curative treatment, we consider first the importance of removing the source of infection and irritation. If a foreign body remains in the wound, search diligently for it, and if possible remove it. If the injury is attended by inflammation, burrowing of pus, destruction of tissue underneath the skin, secure ample and efficient drainage; in other words, convert the wound, as near as you can, from a septic into an aseptic condition. If we are dealing with a painful or tender cicatrix, which by producing peripheral irritation may determine tetanic spasms, it is proper to excise it. We can readily conceive that the infection may have been so mild as to produce only slight changes in the spinal cord, which but for some peripheral irritation would not have resulted in muscular spasms, and these are the cases where the removal of the exciting cause of the spasms is followed by a cure. I recollect a case of a mild form of tetanus, the result of a slight injury at the distal extremity of the index finger, which left a painful, tender scar, where the trismus was always increased by pressure, and which yielded promptly to removal of the exciting cause.

Another practical point in the treatment is the consideration of the propriety of amputation. If we are dealing with a compound comminuted fracture of the leg or arm, attended by all the symptoms of wound infection, and if present indications point towards the fact that the limb, independently of the existence of this complication, could not be saved, it is only rational to resort to amputation. It is, however, proper to state that in the great majority of the cases thus treated the tetanus continued unabated after the operation, and only in exceptional cases has life been saved by this procedure. Recognizing the fact that according to Rokitansky's theory, tetanus simply means "an ascending neuritis from the point of injury to the spinal cord," attempts have been made to arrest the progress of the disease by interrupting the nerve above the disease by nerve section, but results have shown that this operation had no effect in modifying the termination of the disease. You will readily understand *why*, if you assume its central location and its infective character. If tetanus were simply a "neuritis ascendens," we might reasonably expect to arrest the progress of the disease by division of the nerve trunk, by making the section through healthy tissue on the proximal side of the inflamed portion of the nerve. Granted that this operation would be efficient in preventing extension of the inflammatory process, it would not be applicable in all instances, from the inability of the surgeon to locate the disease with sufficient accuracy. Imagine an injury involving the palm of the hand, where we have filaments of different nerves implicated; it would be difficult if not impossible to ascertain in every case which nerve trunk was the seat of irritation. Taking it for granted that the neuritis is simply a local expression of the nerve injury, and that the real cause of tetanus consists in a specific infection, expending itself upon the brain and spinal cord, all efforts at correcting or curing the disease by submitting nerve trunks to operative measures are in discord with the true pathology of the disease. A somewhat similar and more recent operation for the same object as nerve section, we find in nerve stretching. For the last few years it has become the operation for all obscure nervous diseases, such as locomotor ataxia and central irritation of various kinds; consequently it is not surprising that it has been resorted to in the treatment of tetanus.

Benedict collected twenty-four cases of traumatic tetanus treated by nerve-stretching, of which number four recovered. I have stated that the disease in the milder form shows a tendency to cure itself; consequently, all operative measures which have been resorted to for the purpose of arresting its progress must be accepted with a great deal of caution, inasmuch as statistics have shown, on the whole, that twenty-five per cent. have

recovered without operative interference by the ordinary treatment; consequently, we have no proof that these four cases would not have recovered without nerve-stretching. All the possible good that can accrue from operations on nerve-trunks is simply to interrupt the nerve-current between the central disease and the peripheral irritation, and in many instances it is impossible to decide which of the larger trunks connects the two.

The medical treatment consists in the administration of drugs which are known to relieve muscular spasm. In animals tetanized with strychnine the spasms are promptly relieved by injecting hydrate of chloral into the veins. Woorara has been given with a view of relieving muscular spasm. On account of the potency of this remedy, its effects must be carefully watched and its use promptly suspended as soon as its physiological action becomes apparent. It is best administered hypodermatically. Bromide of potassium in large doses is well known to cause cerebral anæmia, and on this account it should be given to relieve the hyperæmia which is always present in the cerebro-spinal centres. A combination best adapted to fulfil the two most urgent indications, to relieve cerebral and spinal congestion and to overcome muscular spasm, are chloral and bromide of potassium. The remedies should be given in large doses, frequently repeated, until the desired result has been obtained. In severe cases, chloroform should be administered by inhalation with a view of relieving urgent symptoms; cold drafts of air, noise, and all forms of peripheral irritation, should be carefully excluded from the patient's room, for the purpose of securing rest, and with a view of not aggravating reflex spasm. Alcoholic stimulants and external heat are indicated when the heart's action has become feeble from general capillary stasis.

Communications.

THE RATIONAL TREATMENT OF BRONCHIAL AND PULMONARY DISEASES BY THE PNEUMATIC CABINET.*

BY W. EVERETT SMITH, M. D. (HARVARD),

Fellow of the Massachusetts Medical Society; Member of the American Medical Association; formerly Asst. Physician to the Massachusetts Home for Intemperate Women.

"Phthisis has been cured by the topical application of appropriate remedial agents."

The use of the Pneumatic Cabinet marks an important era in the treatment of lung diseases. Until within about thirty years, pulmonary consumption was almost universally regarded as an incurable disease. Indeed, it was only the occasional discovery of hardened masses and cavities that had healed over in the lungs of patients that had died of other diseases, that gradually led the medical world to believe that consumption could ever be cured. The possibility of a cure in lung diseases being then conclusively established, the causes of these diseases began to be more carefully studied, with the hope of finally discovering some treatment directed to their removal.

All the methods that have been used hitherto may have their measure of value, but all have failed to work the desired cure, because they were not founded upon a practical and physiological basis; for it is one of the soundest maxims of medicine, says Dr. Austin Flint, that the indications for medical treatment derived from science and from nature should harmonize, and be in accordance with the dictates of common sense.

Theory of the Treatment. — Adequately, then, to combat disease, it is necessary to thoroughly understand the functions and requirements of health; and it is suggestive of the value of the treatment of lung diseases by the pneumatic cabinet that *its development is in harmony with and depends upon physiological principles.* The life of lung tissue depends upon pure air; any interruption or irregularity in this supply means the beginning of lung disease.

The first symptoms of cough, expectoration, whether streaked with blood or not, pain in the chest, long-continued huskiness of voice or hemorrhage, slight in degree though they may be, and often disregarded, are always signs of danger—signs of some unhealthy process either in the bronchial tubes or in the lung itself. A certain portion of the air-passages is irritated or inflamed, and this irritation, if allowed to run unchecked, will oftentimes end in far more serious trouble.

For example, in acute bronchitis, or a "cold," as it is commonly called, as well as in chronic bronchitis, the bronchial tubes are inflamed, swollen, and clogged with a sticky secretion more or less difficult to expel by acts of coughing. So in whooping-cough, a disease that not infrequently leads to the development of consumption, the bronchial inflammation is always a very prominent symptom. In asthma, too, there is always a marked bronchitis, together with

* See also my paper reprinted from the Journal of the American Medical Association, November 14, 1885.

a dilatation of the air-cells themselves (emphysema), which directly hinder the act of respiration and result in a distressing and serious, although not positively dangerous, affection, *unless* bronchitis or pneumonia should occur.

In pleurisy, the presence of water in the cavity of the chest compels the lung to occupy a much smaller space than is natural to it. The lung cells cannot expand, and gradually become closed to the entrance of air, if the pleurisy be of long duration. In pneumonia, on the other hand, certain of the air cells themselves are intensely inflamed, and so filled with blood that they become consolidated or solidified, resembling flesh in appearance, and are perfectly impervious to air. These inflamed portions of the lung are then utterly unfitted for respiratory and aerating purposes, and if the pneumonia become a chronic affair, may possibly never regain the power of properly expanding, unless some means are used to aid the powers of nature.

During all these inflammatory processes in the lung tissue, the act of breathing becomes an effort, the blood is imperfectly purified, strength and flesh are lost, and the whole system suffers. If moreover, in addition to the actual bronchial or lung disease in progress there be any inherited tendency to pulmonary weakness, together with a flat and undeveloped chest, the most favorable conditions exist for definite and serious lung trouble. The germs of disease find a portion of lung or bronchial tube that is weak, inflamed, and kept at rest. This is a quiet home for them, a fertile soil in which to grow and multiply, and they improve their opportunity.

In all this loss of health, however, the patient himself, as a rule, is hopeful; he says he has always, from childhood, been subject to "taking cold;" he is positive that this present trouble is merely temporary, and far from serious; that the cough is simply "bronchial;" that the blood very likely comes from the nose or the back of the mouth; that the pain in the chest is nothing new, but is due merely to a temporary "cold," and that flesh and strength will soon return. *In this very delay lies the greatest danger.* Too late he recognizes that the *golden* opportunity for a *speedy* recovery has passed, and that he must now *struggle* to regain his health and prevent the further ravages of the disease.

Whenever, then, the mucous membrane of the bronchial tubes is swollen and inflamed, as in bronchitis, "bronchial attacks," whooping cough, and asthma, and whenever lung tissue is consolidated or solidified, as in consumption, chronic pleurisy, and pneumonia, the life and healthful activity of the respiratory system is seriously impeded.

To soothe these inflamed portions of the lungs, to expand the consolidated portions, and at the same time to deposit remedial and antiseptic agents in cavities as well as upon the the weak and over-sensitive lung cells and bronchial tubes, is the method and the theory of the treatment of lung and bronchial diseases by the Pneumatic Cabinet.

DESCRIPTION OF THE PNEUMATIC CABINET.

The Cabinet is practically an air-tight chamber, large enough for a patient to sit or stand in. In front is a large plate-glass window, through which passes a gutta percha tube having a stop-cock on the outside, and ending in a trumpet-shape for receiving the medicated spray. The tube within the Cabinet is fitted to a flexible rubber mouth-piece for the patient. The patient enters the Cabinet and seats himself opposite the window. The door is closed, and a partial vacuum is made by an air-pump to the desired degree, as represented by a rise of mercury in a barometer connected with the inside of the Cabinet. The degree of rarefaction is usually that represented by a barometric rise of from one-tenth of an inch to an inch and a half, each tenth of an inch being equivalent to an altitude of 100 feet as regards the removal of external pressure from the chest-walls.

The patient now inserts the inhaling tube in his mouth and compresses the nostrils with the fingers to prevent the escape of air through the nose; the stop-cock is opened, and the outside air of the room rushes into the lungs, carrying with it the medicated spray, which is atomized by a cylinder of compressed air. The effect is a *forced involuntary inspiration* followed by a *forced voluntary expiration.** These respiratory movements are continued for several minutes, but upon the least fatigue the stop-cock is closed, the patient removes the tube from the mouth, and breathes the rarefied air of the Cabinet until ready for another application. The treatment varies in duration from ten to thirty minutes, and is repeated either daily or at intervals of two or three days, the number of applications varying, the greatest number being 105—a case of rapid consumption, which recovered.

*In *ordinary* breathing, on the contrary, the act of inspiration is voluntary, *i. e.*, accomplished by more or less effort, while expiration is involuntary and passive, *i. e.*, a simple elastic contraction of the chest.

Value of the Treatment. — *The peculiar value of this treatment lies in the combination of the medicated spray with the increased strength of the respiratory movements.* A much fuller expansion of the chest is produced than is possible by an ordinary full inspiration, and at the same time the medicated spray being carried to *the very deepest and most remote portions of the lungs* with much greater force than by a natural inspiration, *is deposited upon the bronchial tubes,* even the smallest of them, *as well as in cavities and other diseased and inflamed portions* of the lungs.

The materials, moreover, which have been found most useful as antiseptic inhalations are not mere gases which are mingled with the inspired air and then pass out with it, but they are vapors of soluble bodies* which are deposited upon lung tissue. *Upon every moist bronchial tube, upon the walls of cavities and around, if not within, the areas of inflammation, the inhaled vapor is condensed to render the soil barren for germ growth,* to impregnate lung cells and bronchial mucous membranes with antiseptic material, which we know renders them less fitted for the *cultivation* of germs, so that finally we may be able to supply the vital activity which is lacking in those parts, and prevent the progress of disease.

EFFECT UPON CHEST CAPACITY.

At the same time we must not neglect to consider the beneficial effects of removing the external pressure of the atmosphere from the chest walls. The active and passive movements of the respiratory act being reversed, the breathing takes place not merely with the *tidal* volume of air (which is carried by ordinary inspiration only to the larger bronchial tubes, reaching the lung-cells in obedience simply to the law of the diffusion of gases), but also with the much larger volume of *complemental* air.† When properly conducted, therefore, a gymnastic action is produced, which expands and strengthens not only the diseased, but even the healthy, although undeveloped, chest, and which is beneficial from a mere hygienic standpoint. Indeed, careful tests before and after a course of treatment, have demonstrated an increase in the capacity of the chest of from twenty-five to one hundred per cent., and a corresponding development both of chest measurements and of chest expansion.

I have called this increased action of the chest gymnastic, but I do not mean that its beneficial effects are solely seen in the development of the muscles of the chest walls. On the contrary, it is the mucous membrane of the bronchial tubes and of the lung-cells that is strengthened and invigorated, while the lung-cells themselves are expanded and stimulated into a more vigorous and healthful activity.

EFFECT UPON COUGH AND EXPECTORATION.

The effect of the inhalations upon the cough and expectoration depends not only upon the progress that disease has made upon the lungs, but also upon the choice of remedies that are to be inhaled. In nearly every case, however, there has been noticed a marked decrease of both of these symptoms, although at first the expectoration may be somewhat increased. This increase is due to the fact that the removal of the external pressure has caused such an expansion of air in the bronchial tubes as forcibly to expel secretions, which may have so accumulated as seriously to impede the proper expansion of the air-cells.

EFFECT UPON HEMORRHAGE.

Finally, the influence of this treatment upon the circulation is very instructive and worthy of the most careful study. In brief, we may say, without entering into a scientific discussion of the subject, that the blood-pressure in the large blood-vessels is increased, but that the pressure in the small blood-vessels or capillaries of the lung cells and bronchial tubes is so far decreased as *actually to decrease the liability to pulmonary or bronchial hemorrhage, and in some cases even to arrest the hemorrhage during the attack.* This modification of the capillary blood-pressure can scarcely be other than beneficial to any inflammatory process in the lung tissue.

SUMMARY OF EFFECTS.

To sum up briefly the effects of this treatment in the Cabinet: *The fever, cough, expectoration, and tendency to hemorrhage are all decreased, while the appetite, strength, weight, and vigor of voice, are increased to a marked degree. So, too, there is a disposition to a more restful and refreshing sleep.*

An increased amount of oxygen is absorbed by the system, giving better blood, firmer tone to the heart, and greater strength and regularity to the circulation. The withdrawal of atmospheric pressure from the surface of the body promotes also the healthy secretions

*The principal agents thus far used in the spray have been the bichloride of mercury, iodine, carbolic acid, phenyl, oil of pine needles, benzoin and other balsams, creasote, and camphor.

† The *tidal* or *breathing volume* of air is that air which passes in and out of the lungs with each ordiuary breath. It amounts only to about twenty-five cubic inches. The *complemental* air is that amount which can be taken into the lungs by forced breathing *in addition* to the *tidal* volume, and amounts to about 100 cubic inches

from the skin, and reduces blood pressure in the liver and kidneys. This reduction of pressure in these organs, which are so prone to diseases caused by over-distension with blood, allows them to resume their proper functional activity. *On the other hand, the unhealthy and weakening secretions, the so-called night-sweats, disappear as a rule,* owing to an increased tone and vigor in the sweat-glands.

Diseases that are benefited by this treatment. —Thus far the greatest value of this method has been in the treatment of *consumption at all stages, but especially in the early stages, acute and chronic bronchitis, asthma, emphysema, the chronic remains of whooping cough, and the consolidations resulting from an old pleurisy or pneumonia. It is useful also as a hygienic exercise, to expand a comparatively healthy but undeveloped chest.*

It cannot by any possibility interfere with any of the well-known medicinal and nutritive measures that it may be expedient to employ, and it certainly has been the means of curing pulmonary consumption, even after cavities have been formed.

To treat these various diseases successfully, an ingenious mechanism permits the operator at will either to rarefy the air within the Cabinet to a given degree, or to condense it to a given degree, or alternately to rarefy and condense it, rarefying it with the act of inhalation, and condensing it with the act of exhalation, thus causing a vigorous artificial respiration.

Although the cases that have been reported thus far have certainly given proof of the possibilities of recovery from the most serious of lung diseases, the danger, when looking at such a history of treatment, is that inconsiderate enthusiasm may prevent one from fairly weighing evidence which must in all justness be impartially considered. It is a duty, however, which we owe to humanity, to investigate the subject carefully and without prejudice, patiently developing what is good in the method, and gradually learning what is its proper place in the healing art.

194 *West Brookline street, Boston, Mass.*

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. James H. Hutchinson.

Chronic Cirrhotic Kidney, with Acute Catarrhal Nephritis.

This colored woman, 47 years old, has been in the house before, in very much the same condition that we now find her. This last time she was admitted January 19. When we inquire into her family history we learn that her father died of "gravel," that she has had all the usual diseases of childhood, and later on typhoid fever, variola, and rheumatism. She has had several children, and her menopause occurred suddenly about one year ago. Some time ago she had well marked chills and fever. About six months ago she was admitted to the hospital, complaining of great dyspnœa and orthopnœa, vertigo, œdema of the face and limbs, and she was passing very large quantities of urine. After a while she spat up some blood. At that time the cardiac action was very rapid, and there was an irregular, harsh, presystolic murmur. The urine had a specific gravity of 1025, and contained albumen in abundance, bloody and granular casts. After a course of treatment, which consisted largely of digitalis, she was very much improved and was discharged. Now she is back again, in very much the same condition. Her urine has a specific gravity of 1009; there is no sugar, but we find albumen in abundance, as well as hyaline, bloody, and granular casts. She has great œdema of the face, especially of the eyelids, the abdomen is much distended, and not only pits on pressure, but there is also fluctuation, which indicates to us that we have not only œdema of the cellular tissue, but effusion within the cavity of the abdomen as well. As additional evidence of this effusion, you note how the umbilicus protrudes. The whole body is œdematous. The apex beat of the heart is somewhat displaced to the left, being felt without the line of the nipple. There is a distinct increase of the area of dullness and a distinct musical systolic murmur, heard over the whole area, which indicates mitral insufficiency; and I am not quite sure that I do not hear a murmur over the aortic region, indicating aortic constriction, but it may be that this is a conducted murmur. Sibilant and sonorous rales are heard all over the chest; there is marked œdema of the lungs, which adds materially to the gravity of the case. Now the rheumatism may account for the cardiac trouble, or it may be due to the kidney disease, for we know that this combination is not uncommon. Since the case has not been observed closely, and we are consequently unable to procure a very accurate history, it is hard to say positively what is the exact relationship between the different diseased conditions. The woman has been intemperate; there is more or less œdema of every organ; the condition is a

very critical one, and calls for prompt treatment. The long continuance of the disease, the presence of granular cells, the fact that at times the amount of albumen is very slight, would incline us to the view that the woman has for a foundation a cirrhotic condition of the kidneys, a chronic parenchymatous nephritis. The presence of hyaline casts merely tells us that the disease is chronic, but does not aid us to differentiate the type, as they are common to all chronic forms. Dropsy is not usually marked in cirrhotic kidney, but is a very usual accompaniment of acute catarrhal nephritis; hence the explanation of this case would seem to be (bearing in mind that the woman was here six months ago in a similar condition) that she had and now has an acute attack of catarrhal nephritis superadded to a chronic cirrhotic condition of the kidneys.

The strongest indication in this case is to promptly relieve the œdema. If it could be accomplished by digitalis it would be well, for we would then have, with the diuretic action, a good cardiac tonic; but where the condition is so urgent, I fear that digitalis would not be satisfactory, for its action would be too slow. In this case we are called upon to use hydragogue cathartics; we can use compound jalap pow. der, in drachm doses, or elaterium. In addition to these drugs, we can also use digitalis, more especially for its action on the heart, and Basham's mixture. These measures will very likely relieve the woman for the present, but we cannot expect to do any permanent good where there is evidently so much disease. The chances are in favor of relieving the urgent symptoms, because they have been relieved before when she was in an equally critical condition. We might accomplish much in these cases by a full sweat with pilocarpine, but elaterium is more certain. Hot air or hot vapor-baths and dry cups over the loins are useful; but whatever you do, you must do promptly.

Mitral Regurgitation and Aortic Obstruction.

This woman has been in the hospital several times before. She is twenty-eight years old, and was admitted for the last time on the fifth of January. Her father died of phthisis, but all the other members of her family are living and well. She commenced to menstruate at fifteen, and it was regular and easy for one year, ever since which time she has had much pain at every period. At twelve years of age she had rheumatism, after which she suffered from heart disease and dropsy. Four years ago she was admitted to the hospital suffering from these conditions, and for the same troubles was readmitted eighteen months ago; on both occasions she was very much benefited by treatment. Now we find a systolic mitral murmur, the liver is enlarged, there are rales over the chest, the urine has a specific gravity of 1020, there is albumen, bile, and pus discovered in it. The eyes are very prominent, as is also slightly the thyroid gland; which symptoms, taken in connection with the cardiac disease, at first somewhat inclined me to the belief that we had to do with a case of exophthalmic goitre. On January 9 casts were found in the urine, while on the 12th they were absent. This was not enough to justify the suspicion of exophthalmic goitre. A violently-acting heart is not necessarily due to valvular disease; it is the cause here, but we have not the constant rapidity, independent of exertion, that we find in goitre. The area of cardiac dullness is increased. The apex beat is displaced to the left, probably due to a contraction of this side caused by a pleurisy. There is a distinct, but not loud systolic murmur. Remember that the loudness of the murmur does not indicate the extent of the disease; we may have a very loud murmur due simply to anæmia, when there is really no disease at all. Again, I have frequently noted, as in this case, that the murmur may be very feeble when the patient is weak and exhausted, and grow louder as she increases in strength. This woman has improved very much since she came in. If you take the apex of the heart as a centre and draw a circle with a diameter of one inch, you will have what is known as the mitral area. This murmur, or a murmur, can also be heard posteriorly on the right side of the heart, but it differs from the other in character and intensity. Remember that a conducted murmur will always have the same characters as the original murmur; therefore, when they differ in character, we know that we have two lesions. Here, then, in this case, we have mitral regurgitation and aortic obstruction. A curious and valuable point to be observed about this case, as we will find it in others, is that while the woman maintains her general health in fair condition, she is able to tolerate the heart disease with but little inconvenience, but when she takes cold, or in way her equilibrium becomes deranged, the cardiac mischief makes itself unpleasantly prominent. When she has a few days' rest she always recuperates. The mitral murmur is heard most distinctly at the inferior angle of

the scapula, more so than in front; this is a diagnostic sign in mitral disease. In many cases it is very difficult, even for the best diagnosticians, to differentiate a mitral from an aortic murmur; but when we hear it posteriorly, at the inferior angle of the scapula, we know that it is mitral. It is not, however, usual to hear it *more* distinctly posteriorly, but I think it can be accounted for in this case by the fact that the pleurisy has forced the heart backwards, closer to the posterior wall of the chest.

I will say here a word in reference to the prpriety of paracentesis thoracis for pleuritic effusion, about which there is considerable diversity of opinion. I would consider that it would be proper to resort to this operation when the effusion threatens suffocation, when it is surely purulent, or when diuretics and hydragogue cathartics have failed to remove it. If in all cases we tap simply because there is an effusion, we will usually do more harm than good.

You will often see cases similar to the one before you, and it is therefore important that you should take away with you a clear idea of it. Here we have a diseased heart, superadded to which is an exhausted heart. Of course, the treatment is plain; cardiac tonics are called for, and there is none better than digitalis, especially if there be an effusion. I would give a dessertspoonful of the infusion every three or four hours, where the patient could be watched, though, if preferred, the tincture or the powder could be used. Diuretics would also be indicated if there were effusion, and there is none better than Basham's mixture, which combines diuretic and tonic properties. If there is much fever, quinine would be indicated, and if debility, cod-liver oil. The diet should consist of milk and semi-fluids. But I will enunciate as a golden and imperative rule, that all drugs will be absolutely useless unless you bear in mind the great importance of rest. If I were in this condition myself, I would rather remain in bed with no drugs, than to have all the most approved therapeutic resources and walk about as usual.

Psoriasis.

The student so seldom sees skin diseases that I bring this case before you. The woman has a fractured arm, for which she is being treated in the surgical wards. The eruption, as you see, is squamous, and the scales are very fine. This disease seems to have a peculiar affinity for the elbows and knees. In some places the eruption is only in points, while in others it is in large patches. From these appearances the disease has a variety of names: *Psoriasis punctata, p. guttata, p. umbilaris, p. diffusa,* and because some cases obstinately resist treatment, *p. inveterata.* But in all these forms the disease is the same, and calls for the same treatment. It is a characteristic of this disease that it usually attacks those who are otherwise in good health, which is a point to distingush it from eczema, that usually attacks those who are out of health. It is very common to find this eruption about the junction of the hair and scalp. There is no drug better than Fowler's solution in these cases. Hebra prefers arsenious acid, in doses of $\frac{1}{60}$ of a grain, gradually increased up to the point of tolerance; but I think you will derive very satisfactory results from Fowler's solution, commencing with five-drop doses. If there is constipation or any functional derangement, it must be corrected. In this disease arsenic is almost as much of a specific as quinine in malaria and iodide of potassium in syphilis. Externally, we should use an ointment of chrysophanic acid, five or ten grains to an ounce. This will sometimes cause irritation, and if the fingers used to scratch are put in the eyes, we may have trouble; but there is not this objection to tar ointment, with a little alum. Oxide of zinc, yellow oxide of mercury, or nitrate of mercury ointments may be used. When very diffuse, we may use baths of sulphate of soda. In many cases we will have to vary the external treatment, giving arsenic all the while. The disease generally runs in families.

Medical Societies.

CINCINNATI ACADEMY OF MEDICINE.

Meeting of December 7, 1885.
President, Samuel Nickles, M. D.
Secretary, G. A. Fackler, M. D.

Dr. J. F. Whittaker, Professor of the Theory and Practice of Medicine, Medical College of Ohio, spoke on the subject of

Bright's Disease.

We scarcely have any idea of the results of the researches of Richard Bright, unless we transform ourselves back to the first quarter of this century. Then dropsy was considered a separate disease. The textbooks contained chapters on dropsy. This was, it is true, known to sometimes depend on diseases of the heart and liver. Albumen was found in the urine. Bright displayed

the first anatomical specimen of kidney disease. Bright only described one form of the disease, but the subject was immediately taken in hand by English and French investigators. Frerich, in 1851, illuminated the field more than any one since Bright. Frerich came to believe that Bright's disease commenced as acute, then assumed a chronic form, then later became the shrunken or cirrhotic kidney. Eminent English observers denied this. Bright's disease, they said, commenced as Bright's disease. Partels, in 1871, said it should be called Bright's disease, acute, chronic, cirrhotic, and amyloid. But we cannot always distinguish between these. We generally have the chronic and the amyloid together. Bright's disease seems to be more and more frequent. It is the business of the kidney to carry off refuse matter, whether it be pathological or physiological. Carrying off diseased matter from the body, it becomes diseased. It is attacked by chemical and toxic agents. Diseases also extend from the urethra and bladder. Many a case of kidney disease has its origin in a case of gonorrhœa. I will confine myself chiefly to the theoretical part, and leave the practical to those who may take a part in the discussion. We use to-day the same tests as did Bright. Many others have been invented, but heat still remains the best. Of course, every student knows that the urine must be acid; if not acid, add acetic acid to make it so, otherwise carbonic acid will precipitate the phosphates.

The question is, why does albumen appear in the urine? There have been many theories. It is now definitely known that albumen appears in the urine from a diseased condition of the epithelial coating of the Malphigian coils. The albumen appears transitory in the urine. What is the source of the albumen? It has been demonstrated as an absolute fact that the cause of albumen appearing in the urine is a diseased epithelial coating of the Malphigian coil. If you keep the blood from the kidney mechanically, a change occurs in the epithelial cells, and albumen occurs in the urine. Senator says that the albumen sometimes transudes through the secondary capillaries lower down. Experiments have been made of cutting the kidney from the body and boiling it, and the coagulated albumen is found in the Malphigian tufts; the lighter the pressure the more albumen transudes, and the greater the pressure the less albumen. We estimate the amount of albumen present. This is never more than seven per cent., generally 5.1 per cent., maybe 2.3 per cent. Many practitioners look at the albumen coagulated in the test tube, and say thirty-four, forty, fifty per cent. is albumen. This is not the case. So far as the kidneys themselves appear, they show no lesions. One of the most prominent effects of kidney disease is dropsy. Many explanations are given to account for the dropsy. It has been said, the less urine the more dropsy, and vice versa. Cohnheim thinks it due to a diseased condition of the blood-vessels. This view is, however, not very widely received. Casts give us undoubted evidence of disease. Albumen does not prove positively: casts do. It is a familiar fact that these casts are hyaline—plain, simple, and translucent, composed of albumen. They take the size and shape of the tubes, are never more than one millimètre in length. The bulk of testimony goes to show that the casts are transuded albumen covered externally by cells and debris. The casts show the stage of the disease. Uremia is at all times the most important symptom of Bright's disease. When the kidney ceases its function all can see why water is present in the blood—not only water, but also urea. It has been a familiar experiment that extirpation of the kidney or ligature of the ureters in the lower animals produces vomiting and symptoms of uremia. Urea may be present in the blood, but is eliminated by the skin and other organs so that it does not poison the patient. In these patients the breath smells of urea, is very offensive, and can be recognized by the physician as soon as he enters the room. The French theory that the urea is transformed into carbonate of ammonia, and as such causes trouble, has been exploded. We are compelled to believe that the symptoms of uremia are caused by urea in the blood. The quantity of urea remains the same, but other matter may vary in quantity. Symptoms in the acute form are vomiting and headache. In the chronic form we have one grand mal. The patient lies unconscions, then falls into a deep sleep and awakens to have another. Amaurosis sometimes follows the attack. The pupils react perfectly to the light; the lesions are not in the eye, but central in character. Implications of the nerves and lungs may follow. We may have the asthma uremica. This is most distressing. It lasts weeks and months, and in one case I knew lasted a year. May have pulmonary œdema, which is generally the last symptom before death occurs. Renal asthma is always fatal. Hypertrophy of the heart, usually the left ventricle, occurs. It is present not only in acute perenchymatous

nephritis, but also in the chronic. Perhaps the most obscure point which yet remains is renal pathology. It is only when obscure points do remain that they are investigated with any interest.

Dr. David De Beck said that no general disease came so often before the specialist, and in no disease has the general practitioner received so much aid from the specialist, as the subject under consideration to-night. We have albuminuric retinitis, œdema, hemorrhage implicating the ocular end of the nerve, more particularly involving atrophy. The capillaries become sclerotic, and on section remain open. We have changes on the part of the nerve fibres, neuroglia, varicose thickenings which come crowded with oil drops. More particularly have we changes in the fibres of Müller. These become thickened and exceedingly refractive and sclerotic. These are important changes. In all cases of albuminaric retinitis we have the vessels more or less involved; the arteries which should be $\frac{2}{3}$ to $\frac{1}{2}$ the size of the veins, we have reduced to $\frac{1}{6}$, $\frac{1}{4}$ the size of the veins, the veins remaining about the normal thickness. We notice also the changes due to endarteritis. In this we have degenerative changes taking the lead; we have fatty patches in the retina. This may be a form of papillitis, optic neuritis, or neuro-retinitis from intra-cranial causes. Of greatest importance to the general practitioner is how often do we see these cases. Wagner saw 12 per cent., Frerichs 15 per cent., La Courrier 20 to 25 per cent., Legner 28 per cent., of chronic kidney cases. I myself, out of 22 cases, have seen 6. The general practitioner does not appreciate the finer changes, and his per cent. is low. The specialist appreciates these finer changes, and his per cent. is high. The proper per cent. is probably 20 to 25. It has been proposed by a prominent oculist, that in certain cases of albuminaric retinitis, premature labor be induced. In one case this has been advised and done.

Dr. W. W. Seely said that the previous speaker had omitted one or two clinical points of interest from an ocular standpoint in regard to these eye pictures. It is generally known that this disease of the fundus oculi may improve and the kidney disease grow worse; and *vice versa*, the trouble in the fundus oculi may remain the same, and the vision may markedly improve. It is a curious fact that this disease in the bottom of the eye has been seen in cases of albuminuria due to malaria. I have seen at least one case. The connection between the disease and the appearance in the fundus oculi is very mysterious. I do not think that the attention of even the general practitioner has been sufficiently directed to these manifestations of malaria. I called attention several years ago to a serous effusion into the vitreous humor due to malaria. It had been diagnosed by another gentleman as hemorrhagic effusion. I have seen typical cases of retinitis due to kidney trouble, which in turn was due to malaria.

Dr. R. B. Davey failed to see the connection of the eye trouble with the general disease. A complete study of the eye enables us to advance very little in our treatment of the disease. Nothing has been said concerning the changes in the blood. One very important point is to measure the amount of albumen in the urine. The doctor then reported a case.

Dr. J. H. Taite spoke of the ocular appearance in chronic cases. In 23 cases of puerperal eclampsia he found the eye sensibly affected in 3. In 2 cases one eye alone was affected. In one the vision was almost completely lost for several days. Both cases made a complete recovery. In one case I know of, the patient, a young woman, almost entirely lost the vision of both eyes. She is perfectly healthy otherwise. Many practitioners say we cannot have Bright's disease, acute form, unless we have structural change in the kidney. I think this is erroneous. I have seen the urine return to a normal condition in a few days after puerperal eclampsia. No woman should be allowed to have eclampsia. Every practitioner should make it a rule to visit his patients as soon as engaged to attend them in labor, and carefully examine the urine. If no albumen is found he should examine her again at intervals to be sure there is none present. I have never seen eclampsia recur repeatedly in the same woman. It occurs almost invariably with the first child, with twins, or with women suffering from chronic Bright's disease. In the latter case the induction of premature labor might be considered Even in this case, preventive medicine might be employed successfully.

Dr. C. O. Wright thought it had been the experience of every man to have cases of puerperal eclampsia in which no albumen could be found.

Dr. Taite supposed that in many cases kidney diseases in women is confined to one kidney. We can easily see why this is, from the right oblique pressure of the pregnant womb. Its function may be almost entirely if not entirely stopped. Hence no albumen

in the urine. We have had gentlemen here to-night to tell us of what has been said or done in France or Germany, but few who tell us what they have seen or experienced or reflected. Let us have a little American thought, experience, and independence.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting held January 6, 1886.

Dr. J. J. Chisolm presented the following notes on

A Piece of Iris Living in the Vitreous Chamber.

G. T. S., æt. 59, six months ago, falling down a railroad embankment, received an injury to the right eye. When seen by his family physician six hours after the accident, he was suffering intensely. The lids had already become very much swollen. Upon carefully separating them a wound was discovered at the upper edge of the cornea, from which a thick splinter of wood was protruding. The removal of this bit of wood was accompanied by a bloody aqueous discharges leaving, however, so much blood in the anterior chamber as to conceal the amount of injury done to the eye contents.

The treatment pursued was rest, cold applications, and the internal administration of anodynes. As the swelling subsided and the blood was absorbed, it was found that sight had been so materially impaired as to leave only perception of light. In time, however, the vision slowly improved, till after three months large objects could be again recognized. In the meantime, the left good eye indicated some growing impairment of vision for distant objects, and the spectacles heretofore worn with comfort, no longer permitted easy reading.

This growing defect in vision in the good eye was supposed to be a sign of sympathetic complications, and for this reason the patient was sent to me from his distant home for surgical treatment.

I found the left good eye hyperopic, v $\frac{15}{40}$ with a + $\frac{1}{20}$, his distant vision became $\frac{15}{12}$ even above normal, and he read brilliant type readily with a + $\frac{1}{8}$ lens. His spectacles were + $\frac{1}{12}$, which accounted for his discomfort. At first sight the injured right eye presented every appearance of a successful cataract extirpation.

The iridectomy was large, well shaped, centrally located, and clean to the very ciliary border. The well formed artificial pupil was black, with traces of capsular deposit as is seen after successful cataract operations. He could detect large objects and count fingers readily at four feet, the distance at which I was sitting from him.

In putting a + $\frac{1}{3}$ lens before his injured eye I was surprised to find v $\frac{15}{70}$, and with a + $\frac{1}{2}$ of $\frac{1}{3}$ lens he could make out words in brilliant type.

He complained of something moving about in his eye, which seemed to wave before his sight. By oblique illumination I could see a whitish body in the vitreous. With ophthalmoscopic illumination the examination showed a healthy fundus and clear vitreous, so as to give a perfect retinal picture.

Hanging from the roof of the vitreous chamber, at some little distance behind the thin, partial capsular film, was a flap of membrane apparently one line wide and two lines in length. It was rectangular in shape and of a yellowish white color. Upon its anterior surface could be clearly traced a vessel of some size, which starting at the base ran down through the whole length of the membrane, to the free extremity of the flap.

This piece of living tissue moved to and fro with the movements of the eyeball. This floating membrane in the vitreous, adhering to the upper anterior edge of the choroid, could be nothing else than the missing piece of iris.

The splinter of wood in entering the eye through the upper scleral border of the cornea, had torn the iris in two places from the pupillary border to the ciliary region, in this way punching a piece out of it. This detached bit of iris had been pushed back into the vitreous chamber, carrying with it a portion of its ciliary body. It remained adherent to the ciliary body at one point by a broad base.

The lens must have been injured also at the time of the accident, because through its torn capsule the aqueous humor had been brought in contact with it, to its complete disappearance by absorption.

As there was a broad base to the flap, with ample nourishing blood-vessels, the piece of displaced iris had continued to live. Although it had been bleached and all trace of pigment had disappeared from it, it was yet thick enough to show us translucency. Under ophthalmoscopic examination it showed boldly as a whitish yellow membrane against the healthy red reflex of the fundus. Curiously, the passage made by the splinter into the vitreous chamber had not been invaded by inflammatory deposits. The hyaline structures had taken on no pathological changes and therefore, excellent vision

had been retained to this curiously-injured eye.

Dr. J. Edwin Michael then related

An Unusual Case of Gunshot Wound.

On Christmas night last, about 9 o'clock, he was called to see a large, stout, well-built German, a saloon-keeper by occupation, who had received a pistol wound while engaged in quelling a disturbance in his establishment.

The ball came from a pistol of the "bull dog" pattern, 38-calibre, and was shot from a distance of 12 to 14 feet in front of and a little to the patient's right.

Upon examining the patient it was seen that the point of entrance of the ball was at a spot almost if not directly over the apex beat of the heart.

Later measurements showed the exact location of the perforation to be 3 inches to the left of median line, 1½ inches to right of left nipple line, and ¾ of an inch below a line drawn transversely through the nipple. There was, of course, no probing. The patient was in a condition of extreme shock; stimulants were given, and after a short while consciousness returned. Upon examination by physical signs, wound of the lower lobe of the left lung, and hemorrhage into the pleural cavity of that side, was diagnosed. It was also probable that there was a co-existing pneumothorax of small degree. About eleven o'clock, two hours after the accident, the patient began to complain of much general pain. He became quiet after a hypodermic of morphia and atropia, and continued comparatively easy for a time, when pain again began to be felt, which was again arrested by a repetition of the hypodermic injection.

At the end of twenty hours from the time of the accident the patient died.

The autopsy showed that the bullet had passed through the fifth rib, near its junction with the cartilage, through the pericardium, through the left ventricle, making in its passage an opening at its point of entrance and another at its point of exit, which two openings were connected by a furrow in the ventricular wall, ploughed up by the ball in its passage through the heart. After leaving the heart it had penetrated and passed through the lower lobe of the left lung, fractured the eleventh rib, and imbedded itself in the soft tissues of the back about two inches to the left of the spinal column.

The doctor thought it remarkable that such a ball should have passed through the heart without causing instant death. He had seen one other case in which the heart had been perforated by a 22-calibre ball. In this case, death was practically instantaneous.

In the case under consideration the wound was obliquely through the heart in such a way as to make valve-like openings in the ventricular walls, similar to the openings in the bladder through which the ureters pass —this form of perforation, he thought, prevented what would have been rapid hemorrhage into the pericardium, had the openings been made in a line perpendicular to the plane at the point of entrance of the ball.

During life there was considerable hemorrhage, but he did not think that it came directly from the heart, but was forced from the pleural cavity by the movements of the lung in respiration. The dressing consisted of cloths saturated in bichloride solution.

Dr. J. J. Chisolm said of course we had all heard of the rare case of perforation of the heart and retention of the bullet within its cavity until found there after death. He had seen cases of injury to the heart by bullets, but none of them had lived so long as 20 hours.

Dr. A. B. Arnold next read a most exhaustive paper on

Circumcision,

in which he treated the subject from a moral as well as from a historical and surgical standpoint.

He protests against the practice, not only because he considers it detrimental in robbing the glans of its natural protective covering and thus exposing to irritation those very sensitive Pacinian bodies about the corona. The result of this exposure and consequent irritation, he thought led to habits of masturbation. From the religious point of view he considered it an entirely erroneous idea that a child born of a Hebrew mother was not a Hebrew until circumcision had been performed. It has recently been decided, he said, that a Jew cannot be excluded from fellowship in a Jewish congregation because of the presence of a foreskin.

He described in detail the methods of operating pursued by physicians in the different countries, both civilized and barbarous.

In answer to the question, "Had any hereditary shortening of the prepuce been observed in Hebrew children as a class?" he said he had noticed nothing different in the formation of the foreskin in them from that of other children.

Dr. James Carey Thomas thanked Dr. Arnold for the pleasure he had had in listening to a subject so ably treated.

Dr. Stanley Hall, who was present, was invited to make some remarks upon the subject. He said, after Dr. Arnold's paper, there was left but little for him to say—he had always been more or less in the dark on the subject, but had never had such a flood of light given him upon the topic, as had been afforded by Dr. Arnold's treatise. Some few years since he was in Vienna during a discussion upon the subject, and it was there decided that circumcision was beneficial in lessening the erethric habit, and that it was anticipating what nature would herself do if left to her own course.

Dr. John R. Uhler said that possibly circumcision had its effect upon procreation by lessening the amount of surface tissue to be filled with blood, and thus allowing a greater amount of blood to be supplied to the centre of the organ. This would, he thought, have the effect of increasing the temperature of the body of the organ. Again, he thought that possibly the reason for its having been first practiced in Eastern countries, and especially in the tropics, was that the dry, sandy atmosphere so potent in causing ophthalmia might have such an irritating effect by causing a gritty deposit beneath the foreskin.

Dr. J. Edwin Michael thanked Dr. Arnold for his paper. He had some time since read an article on the subject from a surgical standpoint. In his experience he had been frequently called upon to remove the prepuce because of its inconvenience. As to affecting the sensitiveness and irritability of the glans, he did not see that the operation made any difference whatever, for how very often do we see men with naturally-exposed glans from an abnormally short prepuce. They present no greater degree of sensitiveness. He thought, with some eminent authorities, that the sensitiveness of the glans is increased by circumcision of long prepuce, the irritability decreased.

Dr. A. B. Arnold thinks too much importance has been attached to the part played by the organ in originating venereal desires. The brain is the centre from which impulses arise. He thinks that when sexual impulses are observed in very young children, as is not rarely the case, that here it is not the brain, but some undue irritation to the corona of the glans. It is to protect against the possibility of such irritation that he advocates leaving the natural covering, the prepuce, just as nature has made it.

Dr. John N. McKenzie exhibited a portion of a growth coughed up from the larynx. The patient had suffered from dyspnœa caused by a growth almost completely filling the laryngeal cavity. Laryngoscopic examination revealed the growth to be composed of an oval mass composed of two lobes, divided by a shallow sulcus of what appeared to be fibrous tissue. The throat was so very irritable that local anæsthesia by the cocaine spray was necessary before any manipulation could be satisfactorily carried out. He removed a portion of the growth with the laryngeal forceps. This gave rise to such a degree of irritation that he was obliged to desist and postpone any further attempt at removal until the following day. On the following day dyspnœa was so great that tracheotomy became necessary. On the day succeeding she was attacked with a spell of coughing, and threw off the portion of papillomatous growth here exhibited. Another attempt will be made to remove the growth with the forceps. Another case that he was examining for hoarseness revealed the presence of complete double uvula.

NEW YORK ACADEMY OF MEDICINE.

Annual meeting, January 7, 1886. The President, A. Jacobi, M. D., in the chair.

Contagious Ophthalmia in Public Institutions.

Dr. R. H. Derby, of the committee appointed to make investigations regarding contagious ophthalmia in the asylums and residential schools of New York, said that on the whole the condition of the asylums was not better than at the time of the preliminary report in June last. He read the detailed report regarding three institutions in the city into which children were received to the number of about one thousand, and nearly three hundred of the entire number had contagious eye disease. The ventilation, sewage, and general sanitary condition, was not such as it should be. The committee recommended an enactment by the Legislature providing for a physician attache to each institution receiving children, who should be required to examine the inmates and those about to be admitted with regard to any contagious or infectious disease, particularly eye or skin disease; and it should be compulsory on the authorities of the institution to provide suitable quarantine for all such cases. The minimum of cubic air space for each inmate should be six hundred cubic feet. Failure to comply with these regulations should be considered a misdemeanor.

The annual reports of officers and committees were handed in. It appeared that the academy was out of debt, and the treasury contained over eight hundred dollars. The total number of volumes in the library, including pamphlets and journals, was twenty-seven thousand.

Among other changes in the constitution and by-laws, it was provided that cases relating to ethics should be referred to the council, and the Committee on Ethics was abolished. The Committee on Education was also abolished.

The result of the election was as follows:

Vice-President.—Dr. H. D. Noyes.

Treasurer.—Dr. Cushman.

Trustee.—Dr. Geo. A. Peters.

Committee on Admission.—Dr. Emerson.

Recording Secretary.—Dr. Jacobus.

Corresponding Secretary.—Dr. Wesley M. Carpenter.

Committee on Library.—Dr. Katzenbach and Dr. Johnson.

Delegates to the State Medical Society.—Drs. W. R. Birdsall, R. W. Amidon, A. S. Hunter, Bullard, and Bacon.

Adjournment.

Editorial Department.

Periscope.

On a Febrile Disorder Communicated from Calves, and Accompanied by an Eczematous Eruption.

Dr. T. Frederick Pearse thus writes in the *Brit. Med. Jour.*, August 8:

A case having the above characteristics has lately been under my care, and I have particulars of two other cases. Similar eczematous patches, but of a very mild form compared to that of my case, are said to be frequent on the hands, arms, and face of those having the handling of these diseased calves. The eruption on the animal is called by my patient (a castrator) "ringworm;" but there are certainly not the same acuteness of symptoms or discharge in the animal as in the disease propagated to the human subject. It is more than doubtful whether the disease in the calves is of the nature of "ringworm" at all. I have not had the opportunity of seeing the disease in calves.

The general symptoms, which came on somewhat acutely, were heightened temperature, varying from 99.5° to nearly 102°, with a frequent but weak pulse, moist but coated tongue, foul breath, a feeling of malaise, and general weakness. These have lasted for nearly a month, though they have somewhat improved during the latter half. My patient says that his brother suffered for six weeks during last winter in exactly the same way as himself.

The eruption consists of inflamed patches, somewhat like incipient boils, which burst, but, instead of discharging pus, pour out a very glutinous serous fluid, which quickly dries and forms a hard scab. There is considerable thickening and hardness of the skin around, and some slight enlargement of the lymphatic glands. The eruption is situated all round the chin, and under the jaws on both sides, with isolated patches on the forehead, eyebrows, and cheek. All round the lower margin of the face there is one continuous discharging surface. As soon as the scabs are removed, fresh discharge hardens and forms a scab again.

A question may, perhaps, be raised as to diagnosis. My patient was in perfect health before this attack, and never had an eruption of any kind about him before. It was treated by my *locum tenens*, in its early stages, for eczema, but apparently without the slightest benefit. The surface is hardly extensive enough or associated with sufficient inflammatory appearances, to account for the decided general symptoms. Again, the thickening around the base of the eruption is too hard for acute eczema, and there is not the same swelling of the skin. There is not the same pain or soreness, either, as in acute eczema. I have prescribed quinine (three or four grains), with full doses (thirty minims) of nitro-hydrochloric acid; and, locally, I tried, first, dusting with iodoform-powder; but, finding apparently little benefit from this, it was changed for oleate of mercury, with oleate of zinc as an ointment. The sores have considerably improved, and the man's general condition is nearly restored.

The Influence of Diet on Cancer.

Dr. H. Percy Dunn thus writes to the *Brit. Med. Jour.*, 1885:

That diet has some influence upon the production of cancer is now generally believed. Since Moore first drew attention to the matter, in 1865, whilst discussing the question of the increase of cancerous disease, confirmatory evidence—partly comparative, partly direct—has been produced by several observers. But, in the case of the human subject, an inquiry intended to elicit evidence upon this point is open to certain objections if it is simply limited to the statement of the habits of a person in the matter of eating. For, undeniably, a "large eater" and a "small eater" are only relative terms. Women are universally small eaters; and, whilst full-bloodedness amongst them is quite the exception, they do not generally exhibit an underfed condition. Ladies, as is well known, are averse to eating much, because they are averse to placing themselves in the position of imperiling their "figures," by growing stout. In the case of men, a different state of things prevails. Men often eat largely without necessarily manifesting any trace of their eating habits. Their business occupations enable them to throw off any ulterior effects which full living might be supposed to induce. Consequently, although eating largely, they cannot be said either to eat to excess or to suffer from the food they consume. But a small-eating woman, by leading a life of ease and indolence, might suffer as much from the penalty of good living as a man who ate to excess. Still, inasmuch as it is impossible to assert that food and feeding occupies more than a subordinate position in the category of mundane attractions made accessible for women by nature, it is conceivable that diet has less opportunity of influencing the production of cancer in women than in men. Now, if the terms "large eater" and "small eater" are only relative, as they obviously must be, how can the question of diet in this relation be determined? By using the term plethoric, which is descriptive of a condition exhibited or not by the patient at the time of examination. If plethoric, then the diet, whatever its nature, has been in excess of the person's requirements. If not plethoric, the patient could scarcely be accused of free living, even although the presumption would be in this direction, when further inquiry elicited the fact that good living was the rule. There is little known as yet of the connection between diet and cancer; but, as a matter of opinion, I am disposed to believe that the influence of diet upon cancerous disease is chiefly centred about those persons whose practice throughout life has been to live freely, whose plethora has always been a positive quantity, and whose cancer becomes developed in one of those organs immediately concerned in actively disposing of the surcharge of food ingested.

A Suggestion on the Proper Alternation of Rest with Effort, as Essential to Health and Strength.

Dr. Jacob L. Williams thus writes in the *Jour. American Med. Ass.*, 1885:

In the early part of my professional pupilage, I heard a suggestion from the venerable Dr. John C. Warren, long since deceased, to this effect. He said: "When engaged in a long surgical operation of half an hour or more in duration, the eyes will sometimes become fatigued, and it will be difficult and unsafe to continue the operation with them in that condition. It is better, under such circumstances, to raise the eyes and let them rest upon some object in a distant part of the room, or, if you can leave the operation, step to the window and look out for a minute or two; you will then return with the eyes refreshed, and can see as well as ever." And more recently, one of the most eminent of American oculists has written that "one great cause of injury to vision is the *continuous* application of the eyes to book or work *after* they have become fatigued." This mention is made because the ideas therein contained represent a principle which holds good in the use of any faculty.

There is a very common belief that mere "exercise strengthens," without the recognition of any other element as necessary to that end. And so some seem to think that the more and longer they can exert their faculties, the stronger they must be. As a result, we see fatigue carried to exhaustion, which is another name for weakening or debility.

Instances are common in various occupations and ages of individuals. The youth is too often crowded with study continuously through the day and perhaps part of the night, till the mental process becomes actually debilitated, sometimes permanently. The business or professional man will not, or cannot, pause for rest till he finds that he positively must, and sometimes not then, but drops at his post. The ambitious rower or pedestrian continues his exercise till his strength is absolutely gone, and sometimes his constitution shattered.

In our special department, the practitioner will labor too many hours continuously during the day, and perhaps the evening, till

his nerves shake like so much loose cordage in the winds. And if he does not, as to my knowledge has occurred in one instance at least, fall dead by the chair, he finds a very long vacation needed to bring back a semblance of his former tone.

We also cannot ignore the fact that patients are too often allowed to suffer a continuance of endurance which has required days to recover from, and has sometimes been followed by more serious results. I emphasize the term *continuous* effort, because from that comes the harm when carried beyond the point of simple fatigue, on to the condition of exhaustion; that point, of course, varying in different persons, and in the same person at different times.

This rule, then, should be learned, and the earlier the better, namely: to rest, if possible, just when we are tired, and to let our patients do the same.

Contributions to Practical Surgery.

From the *Edinburgh Med. Jour.* we learn that Prof. John Chiene, in an admirable series of practical notes on every-day surgery, makes, *inter alia*, the following suggestions:

In wounds of the face, the best stitch to use is horse-hair. Unless the wound is of considerable size, no form of drainage is necessary. The best dressing is a pad of salicylic cotton-wool, or corrosive wool, fixed in position with flexible collodion.

The introduction of the sharp spoon into surgical practice has greatly simplified the treatment of lupus. In the use of the sharp spoon, special care must be taken to scrape away the raised edges of the lupoid ulcer, as it is here that the pathological change is advancing. This is best done by scraping from the sound skin toward the centre of the ulcer. After the new formation is completely removed, the best application is a powder which has been introduced into surgical practice by Dr. Lucas Championnière, of Paris. It consists of (1) light carbonate of magnesia, which has been impregnated with the vapor of eucalyptus, (2) powdered benzoine, and (3) iodoform, in equal quantities.

In persistent hemorrhage from the nasal cavity, plugging of the posterior nares should not be done until an attempt has been made to check the hemorrhage by firmly grasping the nose with the finger and thumb, so as completely to prevent any air passing through the cavity in the act of breathing. This simple means, if persistently tried, will in many cases arrest the bleeding. The hemorrhage persists because the clot, which forms at the rupture in the blood-vessel, is displaced by the air being drawn forcibly through the cavity in the attempt of the patient to clear the nostrils. If this air is prevented from passing through the cavity, the clot consolidates in position, and the hemorrhage is checked.

In a reduction of a dislocation of the lower jaw, the patient should be seated on a low stool before the surgeon. In this way the surgeon gets a sufficient leverage, standing above the patient, and the reduction of the dislocation is simplified.

In the division of a tight frænum of the tongue, when a child is tongue-tied, care must be taken not to use the scissors too freely. All that is necessary is, standing behind the patient, to nick the anterior edge of the frænum with the scissors, and to tear with the finger-nail the remainder of the band. In this way hemorrhage, which is apt to be troublesome, is prevented.

In the removal of an elongated uvula, after you have grasped the apex of the uvula, it is to be drawn forward and rendered tense before division. If it is simply grasped, and an attempt made to divide it in its normal position, it is not always an easy matter to effect the object desired. When it is rendered tense, the operation is a very simple one.

Difficulties of Diagnosis in Certain Cases of Cerebral Tumor.

Before the West Kent Medico-Chirurgical Society, January 1, Dr. Hale White read a paper on the Difficulties of Diagnosis in Certain Cases of Cerebral Tumor. The author first related particulars of a case in which no cerebral symptoms whatever were known to be present during life, but at the necropsy the presence of a tubercular mass in the cerebellum was quite accidentally discovered. Then full particulars were given of an interesting case of tumor in the frontal lobe. In this patient, for a long time, the only symptom was headache, and it was not till a short period before death that the presence of optic neuritis was discovered. The patient died suddenly without the advent of any other than these two symptoms. The next case related was one of a woman, in whom a tumor in the region of the occipital and temporo-sphenoidal lobes existed; it was about the size of a Tangerine orange, and produced no symptoms whatever that could with certainty be referred to its presence. It was concluded from these three cases that tumors might exist in the cerebellum, frontal lobes,

and occipital region, and be very difficult of diagnosis. The presence of paralysis of some of the cranial nerves did not necessarily forbid the diagnosis of the presence of a tumor in this region, for if it were of a very great size its pressure might compress the nerves at the base of the skull against the bone. Tumors in the regions just indicated have no special symptoms, such as paralysis; therefore, for their diagnosis we are entirely dependent upon the general symptoms, viz., headache and optic neuritis; vomiting occupying an intermediate position, being partly a general and partly a special symptom of tumors near or in the cerebellum. Even the combination of headache and optic neuritis did not conclusively prove the existence of a cerebral tumor, for a case was brought forward in which both of these symptoms were present, both being due to anæmia, the patient rapidly recovering on treatment with iron; still, the combination of these two symptoms would make one extremely suspicious. The form of headache most likely to be associated with cerebral tumor was next discussed, and it was pointed out how frequently, if not careful, a mistake might be made with myopic patients, who often complained of dimness of sight and headache. The next question raised was as to the means of diagnosing the kind of tumor, but it was pointed out that this was not of so much importance as to diagnose its presence, because one's duty to a patient is always to give large doses of iodide of potassium.

Animals as Medical Practitioners.

The *Medical Record* says that M. G. Delaunay, in a recent communication to the London Biological Society, observed that medicine as practiced by animals is thoroughly empirical; but the same may be said of that practiced by inferior human races, or, in other words, by the majority of the human species. Animals instinctively choose such food as is best suited to them. A large number wash themselves and bathe, as elephants, stags, birds, ants. In fact, man may take a lesson in hygiene from the lower animals. Animals get rid of their parasites by using dust, mud, clay, etc. Those suffering from fever restrict their diet, keep quiet, seek dark and airy places, drink water, and sometimes plunge into it. When a dog has lost its appetite, it eats that species of grass known as dog's grass (*chien dent*), which acts as an emetic and a purgative. Cats also eat grass. Sheep and cows, when ill, seek out certain herbs. An animal suffering from chronic rheumatism always keeps, as far as possible, in the sun. The warrior ants have regularly organized ambulances. Latreille cut the antennæ of the ant, and other ants came and covered the wounded part with a transparent fluid secreted from their mouths. If a chimpanzee be wounded, it stops the bleeding by placing its hand on the wound, or dressing it with leaves and grass. When an animal has a wounded leg or arm hanging on, it completes the amputation by means of its teeth. A dog, on being stung in the muzzle by a viper, was observed to plunge its head repeatedly for several days into running water. This animal eventually recovered. A sporting dog was run over by a carriage. During three weeks in winter it remained lying in a brook, where its food was taken to it. This animal recovered. A terrier hurt its right eye. It remained under a counter, avoiding light and heat, although it habitually kept close to the fire. It adopted a general treatment, rest and abstinence from food. The local treatment consisted in licking the upper surface of the paw, which it applied to the wounded eye, again licking the paw when it became dry. Animals suffering from traumatic fever treat themselves by the continued application of cold, which M. Delaunay considers to be more certain than any of the other methods. In view of these interesting facts, we are, he thinks, forced to admit that hygiene and therapeutics, as practiced by animals, may, in the interest of psychology, be studied with advantage. He could go even farther, and say that veterinary medicine, and perhaps human medicine, could gather from them useful indications, precisely because they are prompted by instincts which are efficacious in the preservation or restoration of health.

Poisoning by the Seed of Datura Stramonium; Two Cases; Recovery.

Dr. P. B. McCutcheon writes in the *New Orleans M. and S. Jour.*, 1885:

On August 21, 1885, about 12 m., I was called to see Mrs. W., and her son, H. C. W., aged 26 years. I found the mother in bed, complaining of headache, a sense of weakness, and great thirst. The pupils of both eyes were widely dilated, the tongue and fauces very dry, pulse rapid. There was partial delirium. I was informed that about eight o'clock the whole surface of the body had become very red and swollen. Neighbors, recognizing that poison of some kind had been swallowed, gave an emetic, which produced frequent vomiting. The only

symptoms that the son presented at the time of my visit, were dilated pupils, thirst, and swollen hands and arms. He says that he first noticed that he could not see distinctly, whilst in the car at 7 a. m., on the way to his work. Very soon thereafter he had confusion of ideas and dryness of throat; when he arrived at his shop about 8 a. m., he was told that he was intoxicated; while attempting to work, he fell to the floor; water was thrown over him, and he recovered sufficiently to get home by means of the cars.

I obtained the following account as bearing on the cause of these symptoms:

On August 20, a friend gave the mother a branch of datura stramonium, to which were still attached the leaves and some capsules, which contained nearly ripe seed. The leaves were stripped from the stalk and mixed with lard, to form a salve; this was done in a skillet. Some coffee was on the table, and a few of the seed from the capsules, which had been opened, became mixed with the coffee. Moreover, the coffee was parched in the same skillet in which the salve had been made.

Next morning this mixture was ground, and an infusion made which was drunk by the mother and son about 6 a. m., and in one hour's time the symptoms of poisoning were manifest as described. By 4 p. m., all these abnormal manifestations had nearly disappeared.

The only treatment that I used was sulphate of morphia in one-eighth grain doses every two or three hours.

Displaced Spleen and Pregnancy.

Much attention has recently been paid to the anatomical or teratological conditions wherein the kidneys or liver are found to be unusually movable. Arguments have been brought forward to show that the condition represents a mere anatomical or physiological peculiarity, or, on the other hand, that it is pathological, and of the nature of hernia. The latter theory is adopted by Landau and others, who also deem pendulous abdomen and uterine displacements to lie within the province of hernia. Dr. Gabriel Engel, of Klausenburg, Transylvania, has published in the *Orvos Természettudományi Értesitö*, a paper on the "Ætiology of Displaced Spleen." In three cases under his observation, two occurred in pregnant women, without interfering either with gestation or labor. The third case was very interesting. A woman suffered from amenorrhœa for sixteen months, and pregnancy had been confidently diagnosed; the patient, cachectic from malaria, had also been seized with acute pains resembling those felt during labor. A large soft tumor filled the lower part of the abdomen and the pelvis. Quinine was administered in all three cases, and the tumors diminished in size. Otherwise, should drugs or an abdominal belt have failed to relieve, Dr. Engel would have recommended extirpation in preference to the artificial induction of atrophy of the spleen by twisting that organ by manipulation applied to the lax abdominal walls, so as to cause obstruction of the vessels of the hilum. Dr. Engel distinguishes between displacement and mere enlargement, although the three cases which he quotes seem, from the satisfactory therapeutic results, to have all been instances of ague-cake. From any point of view it is doubtful if displaced spleen be homologous, pathologically speaking, to movable liver or kidney.

Unusual Effects of Malaria.

Dr. J. J. Norwine thus writes in the *Therapeutic Gazette*, 1885:

Case 1. Mamie M., age 13. Family history good; no syphilis, gout, or rheumatism; has always been a healthy, stout girl, and at present presents a very healthy appearance; menstruated first at the age of 12, and has been regular in frequency, normal in quantity, and without pain during the flow. This, in brief, constitutes the past history. Patient now presents the following symptoms: Three weeks ago she arose from her bed feeling quite well, "but," says her sister, "she was so nervous." This condition has existed ever since, and is gradually growing worse; her rest at night was good after once getting to sleep, probably not awaking during the night; bowels constipated; appetite failing last few days; does not complain much of pain. Upon this history, in connection with a close physical examination, I diagnosed chorea, the result of malarial infection, and upon this basis I gave the patient the usual anti-malarial agent, sulphate of quinine, combined with that most efficient vehicle, the syrup of yerba santa, in doses of 8 grains every two hours, giving four doses daily, and to my satisfaction the patient had entirely recovered on the third day. I should have added that a liberal mercurial purge was given prior to the quinine.

Case 2. Child, age 1½ years, suffered from chronic diarrhœa for over thirty days. The usual treatment was given—astringents, pepsin, bismuth, and tonics—but all seemed to

only relieve for a very short time. At last my attention was called to the fact that the child's bowels were worse every other morning, and I immediately gave sulph. quininæ, gr. iv, until I gave four doses daily, and the child was relieved the second day, and made a rapid recovery. I claim that it was the anti-periodic effect of the quinine, and not the effect of a bitter tonic, that produced the cure, for the result was too quick.

Obstinate Vomiting Cured by the Stomach-Tube.

Dr. Maere has communicated to the Ghent Medical Society a case in which a young woman who had had some mental shock suffered from such extreme irritability of the stomach that nothing whatever could be retained. The bowels also absolutely refused to act. This obstinate constipation was overcome by faradaism applied by means of an insulating sound with a metallic button introduced into the rectum. Nourishment was given by the bowel. At last, as the patient's condition appeared to be somewhat critical, Dr. Maere, after painting the pharynx with a one per cent. solution of cocaine, introduced a Debove's stomach-tube, and poured in a litre of milk and water in equal proportions. This was retained, and afterwards the patient was able to take and retain gradually increasing quantities of liquid nourishment. In a week she was convalescent. The author suggests that the girl's hysterical condition had caused the stomach to contract in the same way as the limbs sometimes do in these cases, and that when this was once forcibly overcome by feeding through the stomach-tube it did not recur. He remarks that painting the pharynx with cocaine is, as has been pointed out by Dr. De la Roche, much more effectual in facilitating the passage of the œsophageal tube than the application of bromide of potassium.

Atrophoderma Pigmentosum.

The pathology of this affection, which has received so many names, appears to be fairly understood as the result of the labors of Kaposi, Neisser, Vidal, Radcliffe Crocker, and others. About thirty-six cases appear to have been placed on record. Dr. White, of Harvard University, describes two cases in the *Journal of Cutaneous and Venereal Diseases*. The cases occurred in a family of Russian Polish Jews. There were seven children in the family, and the two affected were the second and sixth. The first case was a boy aged seventeen, in whom the melanotic and atrophic conditions were well marked, and telangiectasis was evident only about the face. The second case was also a boy, three years old, in whom the only marked morbid condition appeared to be on the face, and to consist of abnormal pigmentation. The author avers that there can be no doubt of the correctness of the diagnosis in the cases, the first of which exhibits everything characteristic of the disease, except the final transformation of parts into malignant growths. White regards the melanosis as the initial lesion, and would so name the disease, adding the terms telangiectodes and atrophica as secondary conditions. Radcliffe Crocker says the disease is admittedly an atrophy of the skin, and suggests the term "atrophoderma pigmentosum."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——*Harper's Monthly*, in all the thirty years that it has come to us, has been among the most interesting and valued of all our exchanges, and one that commends itself with increasing interest as its years increase. Its illustrations are always of the highest order.

——*The Century* is fairly the rival of *The Monthly*, and while sometimes it may not quite equal it, so fully fills a place of its own both in literature and illustration, that it is always more than welcome.

——*St. Nicholas*, the young people's monthly, is beautiful beyond comparison. There is nothing in periodical literature for the young that can equal its charming illustrations and "well-told tales." Mary Mapes Dodge is its very competent conductor.

——*Littell's Living Age*, a valued exchange of more than thirty years, holds a place that belongs to no other magazine. Without illustrations, or any of the modern attractions of monthly or weekly periodical literature, it is their equal, and to many readers their superior. Its weekly contents of choice *English* literature are invaluable.

——Of family newspapers, *Harper's Weekly*, as an illustrated paper, is the first and best in the country. It is always fresh and beautiful, preserving for future generations the notable scenes of the present, while its literary contents are high-toned and valuable.

——*The Germantown Telegraph* also holds a foremost place. Its new editor has, if possible, made it more attractive, while maintaining the *purity* of its character, that has always made it so welcome as a family paper.

——*The Vermont Journal* is of the same standard, well edited, and always interesting.

——The *Bennington Banner*, the *Cincinnati Weekly Gazette*, and the *Trenton Gazette*, are excellent and welcome exchanges.

——Of our religious exchanges, the New York *Evangelist*, the New York *Christian Advocate*, the *Presbyterian Banner*, of Pittsburgh, and *The Presbyterian*, of Philadelphia, are as valuable for their general, historic, and scientific contents as for the information on more strictly religious matters.

——*The Sunday-School Times* is a bright and valuable weekly paper, not only for the Sunday-school teacher, but for the general reader.

BOOK NOTICES.

A Treatise on Bright's Disease of the Kidneys, Its Pathology, Diagnosis and Treatment. By Henry B. Millard, M. D., etc. 8vo., cloth, pp. 264. Wm. Wood & Co., New York.

This is the second edition of Dr. Millard's work, the first having appeared in 1883. It has met with a favorable reception by the profession, and merited it, as it is founded on conscientious, original research, and a wide field of observation both in hospitals and private practice. The author includes chapters on the anatomy of the kidneys, on albuminuria, and on the urinary secretion generally. In this second edition he has included a considerable amount of new matter, bearing especially on the result of recent researches on the nerves of the kidneys, on the tests for albumen, and on the true etiology of what are generally, though he thinks erroneously, termed uræmic accidents. These additions, and others throughout his pages, bring the work down to the latest advances in the pathology of diseases of the kidneys.

Transactions of the State Medical Society of Wisconsin. 8vo., pp. 170. Appleton, Wisconsin, 1885.

Transactions of the Medical and Chirurgical Faculty of the State of Maryland. 8vo., pp. 254. Baltimore, 1885.

In the first of these volumes about one-half of the reading matter is occupied with the Proceedings, the remainder with original articles. The latter contain usually interesting practical material by independent observers. We may mention a discussion of the comparative merits of Syme's and Pirogoff's Operations, by Dr. Meacher; The Treatment of Pyrexia, by Dr. Dodson; Notes on Insanity, by Dr. Wigginson; The Ignorant Use of Ergot, by Dr. Davis, etc.

The Medical and Chirurgical Faculty of Maryland rely more on official reporters to make summaries of the advances in their respective branches than on voluntary papers to fill their volume. It lacks therefore much of the freshness which we find in society transactions where original observation is more assiduously sought for. The reporters generally perform their work faithfully, and render good abstracts. There are also a limited number of "volunteer papers," most of which we have already referred to as sent us in advance reprints. They are usually carefully prepared.

The Principles and Practice of Medicine. By the late Charles Hilton Fagge, M. D., etc. Edited by P. H. Pye-Smith, M. D., etc. Vol. ii., pp. 888, 8vo. P. Blakiston, Son & Co., Philadelphia, 1886.

The excellent character of this work, to which we alluded on the appearance of the first volume a few months ago, is steadily maintained throughout the second and concluding volume now before us.

The contents of this volume embrace the diseases of the heart, alimentary tract, liver, urinary organs, joints, bones, circulatory system, and skin. The last mentioned is added by the editor, whose judicious notes and careful revision increase the value of the work in all its parts. Within its compass there is no other general treatise of recent issue which equals this work for the fullness and accuracy of its information on the whole realm of practice. Dr. Fagge was a man of unusual capacity, and an enthusiast in medicine. From his student days he was singled out by his teachers and associates as one of the most brilliant of his compeers. The present treatise was the great work of his life, and bears throughout marks of the most careful elaboration and extended studies. We have no doubt that it will take, as it deserves, a place at once in the foremost rank of popular text-books on practice. While it is not too large for the reading of the student, it includes in its nigh two thousand pages much that will be instructive to the practitioner of many years' standing.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

TUBERCLE-BACILLI.

Though the number of eminent medical authorities acknowledging the pathogenic character of micro-organisms daily increases, we do not wish to refer here to the still disputed question, but only mention an important discovery by Prof. Voltolini, of Breslau, (*Allg. Med. Centr. Zeit.*, August 15, 1885). One fact is recognized by all: the presence of tubercle-bacilli in the sputa or in any other morbid discharge (as from the ear, etc.) of a patient is a sure proof of the tubercular infection of the individual, while their absence does by no means determine the contrary.

It might thus appear very easy to discover the tubercular taint in a person. Such really is the case, but the naked truth remains that it is occasionally exceedingly difficult to prove the presence of tubercle-bacilli. As well known, the microbes of lepra and of lupus so greatly resemble each other and those of tubercle, that in all such doubtful cases only the inoculation of an animal by the suspicious material or the pure culture of the bacilli can settle the point. But in both cases we have to wait at least a month before we can establish a correct diagnosis, for in the one we have to look for the result of the artificial infection, and in the other we have to watch the development of the species under pure culture. Many different methods have been proposed during the last year, to overcome this difficulty and to find a way which would enable us at once to recognize the true tubercle-bacilli from those of lepra and of lupus; but such have been scarcely reported ere some investigator proved their fallacy or unreliability.

Voltolini, however, seems to have discovered a procedure which promises the long-desired aid. This procedure is as follows: After the sputum or the pus has been treated in the usual manner on the watch-glass, it is allowed to dry thoroughly in the atmosphere, and the glass then drawn in the well-known way through an alcohol flame. The glass is then taken hold of by brass pincers, or, still better, glass pincers, and dipped *quite slowly* into the strongest undiluted nitric acid, *i. e.*, the acidum nitricum fumens of 145 to 150 specific gravity; it is then taken out just as slowly, and at once dipped into a vessel containing pure water, and there rinsed. The thus prepared material is then dried and afterward placed into the coloring fluid, according to the usual method, and in this the floating glass is permitted to remain for 24 hours, when the color is removed with diluted nitric acid. For the first coloring process

fuchsin, for the second a solution of malachit, is employed by V. The fuming nitric acid used must each time be a fresh preparation, as it at once attracts the water from the atmosphere, and by giving off nitrous vapor changes to common nitric acid, which no longer retains the property of the fuming acid.

Tubercle bacilli thus treated perfectly retain their form, shape, and color, only their contents have undergone an alteration; their interior appears as little nodules attached to each other like a chain of pearls. The bacilli, therefore, seem to consist of a hyaline wall and coagulable contents.

Neither the bacilli of lupus nor those of lepra show the same changes. This "chain-of-pearls" appearance, being characteristic of tubercle bacilli alone, may well serve, therefore, for the differential diagnosis of the three kinds of micro-organisms mentioned, while the method will permit us, henceforth, at once to establish the presence of tubercle bacilli without having to await the results of inoculation or of pure culture.

ANTIPYRIN IN TUBERCULOSIS.

The Medical and Surgical Reporter brought recently several reports concerning the antifebrile effect of antipyrin. In the meeting of June 6, 1885, of the Paris Medical Society, Dr. Daremberg greatly added to our knowledge of the new remedy by giving the results of his observations of the effect of antipyrin in tuberculosis.

According to him, the effect of antipyrin is a rapid but transient one, and for this reason special precautions have to be taken in administering this drug in phthisis, as such patients rarely have two days in succession the same type of fever.

Such individuals ought to take the first dose of the remedy (16 grains) before the fever symptoms appear; ere, therefore, the temperature has reached 101°. Should the temperature ascend more than one-half degree per hour, then a second dose has to be administered. If the thermometer indicate an increase of but one-quarter of a degree an hour before a meal, then the dose must be at once renewed, as digestion might otherwise bring on the fever. But there must always be one full hour between the taking of a dose and the meal. If the remedy is administered after the fever has already commenced, profuse sweats, vomiting, and debility then are the disagreeable side-effects, and in these cases the dose has to be doubled to obtain the same result.

In this manner consumptives may use for months daily 48 to 96 grains of antipyrin with the result that patients, who would otherwise be confined to their bed, walk about, evince appetite, and their lung affection appears to have become stationary, though probably progressing, but they enjoy in general a well-feeling, as the annoyances due to the fever no longer exist.

In cases of acute attacks of fever of short duration, it is better to administer antipyrin at the beginning of the febrile seizure, as its diaphoretic action is rather desired. But it is well in such cases to renew the dose at night to prevent a recurrence of the fever during sleep, a fact apt to occur. Thus, a night of rest is secured without the necessity of having recourse to narcotics.

Dr. Dujardin-Beaumetz confirmed the great antifebrile action of antipyrin in phthisis, but cautions against too large a dose, and considers 8 grains fully sufficient for the purpose indicated. As the main reason for this view, he mentions the fact, that sweats are anyhow annoying to consumptives, who suffer from them so frequently in consequence of their disease. Besides, large doses appeared to him to diminish the appetite.

From these and other reports, it is apparent that we have in antipyrin a valuable antifebrile remedy in pulmonary phthisis.

Notes and Comments.

Unpleasant Effects of Antipyrin.

While of undoubted value in reducing temperature, there can be no question but that this drug does occasionally produce some very unpleasant effects. The following case in point Dr. W. Graham reports in the *Canada Lancet:*

On the 7th of October he was called to Mrs. B., æt. 45, a patient in the fourth week of typhoid, whom he had been attending, and considered convalescent. Her temperature was 103.6°, pulse 120, respiration 30, fine crepitation throughout the lower portion of both lungs. He thought antipyrin the best selection as an antipyretic, judging that it would produce less depression than either quinine or salicylate of soda. He happened to have with him just one drachm, and divided it into five equal powders of two grains each, of which he ordered one every three hours. Next morning early, a messenger was sent with the unwelcome news that the patient was dying. On his arrival he found her in a state of severe collapse. Cold per-

spiration stood in drops over her face and parts of her body, cold hands and feet, temperature 95°, pulse feeble and flickering, impossible to count it. He was, indeed, alarmed, and expected to lose his patient. He immediately gave her ammon. carb. and digitalis, with whisky at short intervals, and applied artificial heat around the body, and was very very much pleased to find that this treatment counteracted the unpleasant symptoms, and she ultimately recovered. Two or three days afterwards her daughter drew his attention to a patch of purpuric maculæ about the size of the palm of the hand on the back, just below the seventh cervical vertebra. This was, no doubt, the characteristic eruption that results from the use of antipyrin, but it was not observed on any other part of the body.

A Fatal Case of Nitric Acid Poisoning.

Dr. Dyce Duckworth thus writes in the *Med. Press*, November 8:

A city merchant, æt. 29, was admitted to St. Bartholomew's Hospital on February 11, 1885, with the history of having swallowed about an ounce of strong nitric acid shortly before. He had been seen by a surgeon, and was found vomiting. Lime water was given to him. He was supposed to have had his luncheon before he took the poison. Calcined magnesia in milk was given freely, and the vomit, previously acid, became alkaline. Opium was given per rectum, and linseed and opiate poultices were laid on the abdomen. The suffering was intense; retching and vomiting; collapse followed. Nutrient enemata with brandy and opium were given. His cough was troublesome; next day there was relief from the opium. The urine contained blood on two occasions, and albumen twice afterwards. Vomiting and retching persisted at intervals, and the pulse became running. Shreds of putrid mucous membrane were ejected. The temperature rose on the fourth day to 102.2°. Diarrhœa set in, but no blood was passed. There was a suspicion of pericarditis. The patient nearly sank on two occasions, but was revived by nutrient enemata with brandy. On the fifth day he was so much better that his friends believed that he was recovering. He died one hundred hours after taking the acid. On examination there were signs of inflammation at the fauces, and down the œsophagus, stomach, duodenum, and as far as the jejunum. The stomach was contracted, but not perforated. Some local peritonitis over the stomach and liver, but no general peritonitis. The pericardium was sticky. He took in all over an ounce of laudanum while under treatment.

Symptoms Resulting from Swallowing a Caterpillar.

Although we will rarely be called upon to treat a patient who has swallowed a caterpillar, yet should such a curious case occur, it will be well not to be taken unawares; hence we note that Dr. George M. Waters, of Columbus, O., thus writes to the *Med. Record:*

"On November 10 I was called to prescribe for a child seven months old. From the parents I learned that the patient had been in good health previous to 2 p. m., and at that time awoke from a sound sleep with a scream, and appeared to be choking. Nothing could be found in the throat to account for these peculiar actions, but considerable redness was noticed about the fauces. At 8 p. m., I found the throat intensely inflamed, a slight elevation of temperature, pulse feeble and rapid, and the patient very restless. The following morning the throat inflammation had subsided, but the temperature had reached 102° F., there were symptoms of intense gastric distress, and the face, body, and upper extremities were covered with an eruption resembling a severe case of urticaria. Bismuth and oil were ordered, with a mild opiate. On the morning of November 12, the eruption, with exceptional spots, had disappeared, the temperature had fallen to 99.5°, and there were no indications of pain. The patient was much better, and well it might be, for with the first free stool was passed the body of a caterpillar an inch and a half long, and larger than the common lead pencil; the hair had been completely stripped from the body, which was complete and covered with mucus. With the two following stools came the brown hair of the caterpillar. This was followed by an inflammatory diarrhœa for three days, when the child began to improve rapidly, and is now in good health."

Conception while the Uterus Contained a Placenta.

Dr. W. M. Trow, of Northampton, Mass., gives an account of the following case to the *Medical Record:*

"Mrs. ———, a fleshy woman, and the mother of three children, regular in her periodicals, except during pregnancy, passed her period in February, 1885. In March she was normally unwell, and was regular

till August, which she passed. In September she again menstruated. In October she was taken with considerable flow and severe pain, which continued for twenty-four hours, when I was called to see her. On my arrival I found a three months' fœtus, which she expelled just before my entering the house. The placenta was partially detached, and occupied the mouth of the uterus. Under the influence of ergot it came away in a short time in a normal condition. The following day she was feeling well; the flow as usual in such cases. Four days after, I was again called, and found that she had been flowing twenty-four hours, and suffering severe pain most of that time. An examination revealed the mouth of the uterus open enough to admit two fingers, and occupied by a fleshy mass which was firmly attached to its fundus. I gave chloroform and introduced my hand into the vagina, when I was able to detach the mass, which was at once expelled. It proved to be a placenta as large as is usually found in a conception of four or five months. Pain and flowing at once ceased, and she made a fair recovery. This was an unique case with me in an experience of some thirty years."

Cocaine in Vaginismus.

Dr. J. Schrank thus concludes an article in the *Louisville Med. News*, November 28:

"For promoting dilatation the favorable action of cocaine commends it above every other means hitherto employed. While efforts at dilatation, after penciling in the ordinary way, advance only gradually, and to the patient, when not actually intolerable, are exceedingly burdensome, patients deport themselves with the greatest indifference under such efforts made during cocaine narcosis, for they scarcely feel the dilating instrument.

"The cure of vaginismus can then first be regarded as complete, when by dilatation efforts the vagina has been enlarged to the extent that no abrasion of the hymeno-vaginal lacerations, nor of the spots where they existed, takes place during coitus.

"Finally, in a medico-legal aspect, cocaine has also a great significance, since penciling with a solution of this drug renders coitus possible without particular pain, and thus obviates marital troubles."

Spasm of the Sphincter Ani.

This little muscle seems to be an exceedingly important one as regards our comfort or discomfort. We all know how very painful a fissure may be made by its contraction, and we are pleased to call attention to its importance by noting the following conclusions of Dr. T. Pridgin Teale, in the *London Med. Times*, November 28:

1. That spasm of the sphincter ani, as a cause of constipation, suffering, and ill-health, is often overlooked, and patients are allowed to suffer for years who might be cured in five minutes.

2. That spasm of the sphincter can be arrested by forcible dilatation more satisfactorily, more certainly, more scientifically, and with greater safety, than by division by the knife.

3. That in all operations on the rectum and anus, dilatation of the sphincter is an essential, almost an indispensable element in the treatment.

Maternal Impressions and Congenital Deformities.

The following very peculiar cases are of interest in this connection. Dr. George Harvey reports them in the *Brit. Med. Jour.*, December 5, 1885:

A few years ago he confined a woman twice successively of a headless child; in each case she had been frightened by a man's head suddenly appearing around the corner of her house. Both confinements occurred in the early stage of pregnancy. Quite recently he attended Mrs. S., a primipara, whom he delivered of a male child with a well-marked hare-lip. The father has one, but in a very modified form, so much so that it is hardly perceptible. At no period of gestation did her mind revert to her husband's physical defect; but, immediately after delivery, she asked if the child's lip was "all right," and this was the first thought she gave to it.

The Physiological Effects of Guaranine.

In the *Polyclinic* (January 15th), Dr. Thos. J. Mays, having made a series of experiments, thus sums up these effects:

1. That it affects both sensory and motor nerves; the former before the latter.

2. That it paralyzes sensation and motion from the spinal centres, and not, like brucine and cocaine, from the periphery.

3. That it produces hyperæsthesia of the whole body, and afterward convulsions.

4. That its convulsions are spinal, and not cerebral.

5. That it first increases and then decreases respiration.

6. That it differs in its action from that of caffeine, in that it has a stronger affinity for sensory, and less for motor nerves, and that it is more analogous to theine in its action.

Strychnia in Post-partum Hemorrhage.

If post-partum hemorrhage be due to nerve exhaustion, as we can readily suppose, we can understand how strychnia would prove beneficial. At any rate, Dr. Joseph Thompson tells us in the *Brit. Med. Jour.*, December 5, that it is. He knows of several cases where there was a previous history of flooding after labor, but where, when strychnine had been given beforehand, no hemorrhage came on. Strychnine has, no doubt, a marked influence in preventing *post-partum* hemorrhage. He usually gives five-minim doses of the liquor strychniæ in tincture of orange-peel three times daily for a month or six weeks before the expected time, and he cannot recall any case of flooding where it has been given in this way.

Unilateral Œdema.

A case is reported by Dr. Bassi in the *Rivista Inter. di Med. e Chir.*, in which an hysterical young woman presented the curious phenomenon of a unilateral œdema that appeared with each menstrual period. There was no other derangement of general health, although the patient is described as delicate. The œdema was absolutely limited to the right half of the body, but there was no alteration in the color, the temperature, or the sensitiveness of the two sides, although less irritation was necessary to produce reddening of the skin on the right side. Concurrently with this temporary œdema there were signs of congestion of the lung on the same side, and the right ovary was painful. Complete anæsthesia of both corneæ and of the fauces was observed.

The Supra-pubic Operation of Lithotomy.

Sir Henry Thompson, who is the greatest living authority on this subject, thus concludes a paper in the *Lancet*, December 5:

"I am satisfied that the operation described is well adapted for tumors of the bladder when ascertained to be of large size, and when they are not merely simple polypoid growths of a simple kind, which are easily removed through the perineal incision. I adopt, also, a modification of the proceeding for those cases in which a perineal exploration has first been made, and in which, therefore, the bladder cannot be distended; a modification equally applicable to the cases of women in whom the same condition practically exists. This I shall show on a subsequent occasion."

Meningo-Encephalocele.

A remarkably large meningo-encephalocele springing from the region of the anterior fontanelle, in a female child aged two months and a half, was shown before the Medical Society of the Mauritius by Dr. Laurent, a graduate of the University of London. The shape of the tumor was reniform, and it had somewhat the aspect of an elephantoid scrotum, and was pedunculated. It was twice the size of the fœtal head. The tumor was removed with strict antiseptic precautions, but the infant collapsed. The mother of the child had been shocked, when she was in the second month of pregnancy, at the sight of an elephantoid scrotum exhibited to a crowd by a drunken man.

Fixed Vocal Band in Lesion of the Recurrent Laryngeal—Paralysis or Spasm?

There is under observation in the Throat Department of the Philadelphia Polyclinic a case of aneurism of the arch of the aorta and left subclavian artery, producing fixation of the left vocal cord in the median line. The patient speaks in an abnormally high-pitched, stridulous voice; indicating tension rather than relaxation of the band. This suggests the possibility that the affection might be a tonic spasm of the adductor group of muscles, or closers of the glottis (Krause), rather than paralysis of the abductor muscle, the opener of the glottis, to which this position of the vocal band is generally attributed.

Blood-letting Extraordinary.

The *Med. Record* says that M. Thevenau, of Nivernais, according to the *Revue Médicale*, had under his care the wife of a sheriff named Gignault, twenty-four years old, whom he bled, in the course of nine months, from September, 1726, to June 1727, 3,904 times. The woman still lived, and was bled 651 times more in the next six weeks. Bleeding, it appears, was the only means of giving the woman relief, and it was accordingly practiced most industriously for three and a quarter years, the number at the expiration of that period reaching the very respectable figure of 26,230. It is not stated why the phlebotomy was discontinued at this time, but possibly the patient died.

Herpes of Pharynx.

One of those rare cases of herpes of the pharynx, in the vesicular stage, was seen at the Throat Department of the Philadelphia Polyclinic in September.

The patient, a boy nine years old, had complained for about four days of sore throat, with slight constitutional disturbance. On examination several vesicles were seen on the pharynx and pharyngeal side of the left posterior half arch.

Later, vesicles developed on the tonsil and soft and hard palate, and finally, on the lip and nose. These vesicles soon broke, leaving small ulcers, which healed in the course of a week.

Chronic Ulceration of the Face.

In the *Lancet*, December 5, Mr. Juler reports two cases of chronic ulceration of the face resulting from laryngeal fistula. The treatment which had been most successful had consisted (1) in removal of the obstruction, and (2) in complete removal of the thickened tissue. A Volkmann's scoop was used for scraping the ulcerated surface, and skin-grafts had led to rapid healing, without any noticeable scarring or contraction of the skin.

Correspondence.

BERLIN CORRESPONDENCE.

The Medical Faculty of the Berlin University.

Eds. Med. and Surg. Reporter:—

The important changes and improvements which have been taking place during the last few years in all parts of the capital are also noticeable in medicine—great discoveries have been made, and medical science is becoming larger and more extensive daily. As a consequence, the time of study has been increased to nine terms, and it is questionable if this is sufficient. Many voices had been raised for ten terms, and possibly that had been better, for it is not alone the extensiveness but the difficulty of the subject which requires long and concentrated study. Possibly every medical student will remember the confusion into which the study of anatomy threw him. One is overweighted by the long and difficult names. I shall never forget how old Professor Reichert, in one of his lectures, having named the different bones and ligaments, nerves, arteries, veins, muscles, etc., and noticing our perplexed and horrified faces, remarked, "Do not be alarmed, gentlemen; when I began the study of anatomy I believed as you do now, that I should never be able to master it, and now I am Reichert."

Splendid scholar as he was, soulful and enthusiastic in everything pertaining to science, kind and affectionate to his pupils, he could yet scarcely fill the requirements so large a university calls for from its leader, in his later years. An old man, with snow-white hair, he was present and active from 8 a. m. till 2 p. m., but he, an old man, could no longer have the necessary energy and activity required.

It was a lucky move of Berlin to select Waldeyer. He combines the qualities of a great scholar with those of an excellent teacher. His theoretical lectures are very popular, for he speaks with precision and an earnestness which fascinates his hearers.

But the grave point in the study of anatomy is in practical work in dissection. As in all large universities, there are difficulties here; although the material offered to the student is large, still the crush on the part of the student is so enormous that it requires great judgment and disposing talent to do justice to all; and just here Waldeyer is successful. He understands how to use the material fully and to the best advantage. He who has received a *part of a dead body* is obliged to pass an examination at the end of the week with respect to it. As a rule, Waldeyer himself examines. Only when the pupil has thoroughly mastered the object does he receive a new one. If it is not mastered, the student must work and study it further. In this manner two objects are reached—the student is obliged to earnestly study, and waste of the costly material is prevented.

Professor Hartmann continues as professor. Each professor has an assistant, who helps in giving the students the necessary instruction in the preparing. Hartmann reads on osteology, syndesmology, and anthropology of the primitive people. Waldeyer reads on anatomy and embryology.

In physiology nothing is changed. Prof. Du Bois Raymond teaches this in his class, and his spirited delivery, the elegance and precision of his experiments, make this one of the most interesting. During the summer term he lectures on the physiology of the muscles and nerves, a department which he has specially cultivated.

Every Monday evening during the winter, he gives his celebrated lecture on "Some Natural Scientific Discoveries of Late

Times." His words are listened to by more than five hundred persons, not only students, but teachers, officers, and others.

With regard to chemistry, botany, and physics, no alterations have been made. Hofmann, Helmholz, Schwendener, and Eichler, teach these. But we will mention more especially Christiani, professor extraordinary. It may be said that he has created a new branch, it is physic for medical men. For a number of years he has endeavored to acquaint medical men whose knowledge in general of physics might be small, with such physical facts as are related to medicine. He reads experimental medical physics, holds courses on pharmaceutical physics, and has a special class on "Die Mattematische Physic zum Behufe der Physiologischen Physic," for those who may wish to enter more deeply into science.

With the mention of pathological anatomy we arrive at the best of the Berlin University. He who has studied here has had the good fortune to have the personal instruction of the man who has brought about mighty changes in medicine—a man of whom all those connected with medicine can learn. In the theoretical lectures in winter, Virchow treats of general, in summer of special pathology. I believe Virchow needs a cyclus of six years to finish special pathology.

But here, also, the grave point lies in practical work—six times weekly for two hours, which, however, are oftener three and four, practical courses of pathological anatomy are announced. Once a week dissections take place. Here the students are to learn to make a correct autopsy; they themselves dissect, and are required to write down what they have found.

Twice during the week there are practical studies which serve towards the microscopical recognition of pathological changes. A large number of subjects for demonstration are at hand. Virchow connects his lectures with these; in his usual clear manner he reviews the objects, demonstrates the symptoms, and then hands round the objects, with the necessary explanations.

These courses, which are as entertaining as instructive, often extend to four hours.

Three days in the week are given to microscopical technic and to the microscopical recognition of pathological changes. And here the name of the man deserves to be mentioned who, by his extraordinary diligence and perseverance in his work for the Berlin University, deserves credit. I mean Mr. Grawitz. He directs these courses independently, and in an easy, graceful manner reviews the changes which are in the object to be examined, shows what is to be found, and explains this still clearer, with good drawings; then the students begin work, and Grawitz goes from one to the other—very often there are more than eighty students present—and superintends the work of each, constantly demonstrating and examining; he controls the students' preparations, helps the unskilful to prepare such, and is indefatigable. It is not astonishing that he is exceedingly popular, and was greeted with unanimous joy on his return from Greifswald, where he had been called to substitute Professor Grohé.

Passing on to clinical instruction, we should now consider internal clinics and surgery. We shall return to the former, which has experienced important changes, in a later letter; for the present, I shall merely say a few words on surgery.

I cannot possibly describe surgical instruction in Berlin as otherwise than inefficient, and Berlin shares this fate with all universities. The surgical clinics are in the hands of Bardeleben and Bergmann, both first-class scholars, skilful operators, and admirable teachers.

Bergmann, especially, understands how to hold his hearers by his vigorous diction. When he treats on a case and seeks to lead up to a diagnosis, every attentive hearer works with him mentally, and seeks to form the diagnosis. And this is a consequence of his interesting discourse, for very little can be seen—and that is just where the inefficiency mentioned above lies in a nut-shell.

Bergmann's method is not to be underrated; but nothing can substitute a clear viewing of an operation, without which no one can become a good surgeon. Now, it is a deplorable fact that in Bardeleben's, as well as in Bergmann's clinic, everything can be seen except an operation. It is especially aggravating to see the backs of the innumerable assistants, whose persons fill up the last chink through which we might possibly catch a glimpse of the operation going on.

Of course, I understand that in a large circle of listeners, it is very difficult to afford every student an ocular view, but in some way the fact that nothing is to be seen should be remedied; some change should certainly be tried towards a better state of affairs.

The medical man of a large town does not need to undertake surgical cases; there are surgical hospitals for that purpose. But the doctor in a small town, what is he to do? He is obliged to study surgery thoroughly and carefully. That which can be learned

in the polyclinics and in the courses of assistants is not sufficient. There is but one way to learn surgery, and that is to be practically active in a hospital.

It is true that all could not be satisfied, but in two respects affairs might be altered for the better. In the first place, situations for volunteers might be established in all surgical clinics and in all large hospitals, where young physicians or advanced students would find opportunities to see closely the operation, and if possible assist. Schroeder, in his women-clinic, has introduced this, and he should be imitated. If, say, in ten hospitals ten volunteers were engaged at the same time, and remained half a year, in Berlin alone two hundred medical men annually could gain the knowledge of surgery necessary in their practice.

Then also the advantages that military students have over non-military ones is highly unjust. Such pupils of the Friedrich-Wilhelm institute who will bind themselves to serve later on in the army as military physicians for the same length of time that they have previously studied, are allowed to practically work in the Charité by passing over all clinical departments and working there as under-physicians.

The Charité is by far the largest hospital in Germany; it absorbs a large part of the material; it is, so to say, the clinical institute of the university. That it, therefore, should offer the military students such an important advantage over the others, is hard and unjust.

The places for under-physicians in the Charité should not be the privilege of the military student, but should be given according to the merit, the efficiency of any pupil. The number of such places should also be increased, and as already mentioned, new ones should be created in hospitals not necessarily in connection with the university.

To close, permit me to say that such institutions, if called into activity, might be a blessing not only with regard to surgery, but in other clinical departments. L. C.

Berlin 2, 1, 1886.

Fracture of Skull, with Loss of Cerebral Substance.

Eds. Med. and Surg. Reporter:

On the evening of September 15, 1885, the undersigned was hastily summoned to attend a boy, aged ten years, who had fallen from a swing, striking his head against an upright plank. I found the patient in a comatose condition, with his brains oozing from a fracture of the skull at the antero-superior part of the left parietal bone, the fracture extending from near the coronal suture posteriorly, and forming a quadrangle in size about 2x2½ inches, with the anterior edge driven in to brain about one inch, and posterior edge still adherent to skull, and presenting a hinge appearance. A portion of the brain, measuring f.℥ss, was detached in a lump, and is now in my office.

My friend, Dr. Benj. Pearson, assisted me in trephining the skull in two places, when, with some difficulty, we succeeded in raising the depressed bone. Dr. Pearson agreed with me in the decision that there had been lost f.℥ij of the cerebral substance.

The patient remained comatose for thirty hours. On the second day after the accident, during my morning visit, I noticed his eyes turn after me as I moved around the bed. He was very restless, and on my inquiring if he wanted to pass water, to my surprise he said "Yes," the first intelligent word he had spoken. He was raised up in bed and passed water freely into a vessel for the first time, while conscious, since the accident. He lay down, and at my request protruded his tongue for my inspection, although he was still very dull, and the request had to be repeated several times before he seemed to comprehend. During the day he began to chew his food when inserted into his mouth, and notwithstanding the fact that his tongue was heavily coated with a whitish fur, he seemed to relish it well.

On the fourth day he knew his mother and one of the neighbors, but others of them he did not recognize. He would now open his mouth for gruel, it being fed to him with a small spoon.

On fifth day he protruded his tongue without hesitation. On seventh day tongue was almost clean, and boy had a fair appetite. The temperature ranged from 97.8° to 100°; the pulse from 64 to 112. On twenty-first day he was taken home, a distance of three miles, and from this time he gradually improved. The wound discharged for about ten weeks, when it entirely healed. His mind is not in the least impaired, so far as any one is able to judge at this time. He has been attending school, and seems to learn as fast as the other children. His treatment consisted of bro. pot., tr. verat. viride (Norwood's), and continual applications of ice-water to his head, with an occasional calomel purge, guarded with a little opium. After a time, pot. iodid. was substituted for the bromide, and later the others were discontinued. This, to me, was a remarkably interesting case, and thinking that

it might be of interest to some of your readers, and that it might be the means of drawing out some other country doctor's experience in a similar or dissimilar isolated case, I concluded to report it. If either proves to be the result, I shall feel amply repaid.

W. L. DeWolfe, M. D.

Coaltown, Pa., January 24, 1886.

News and Miscellany.

The Peril of Physicians.

Those who have followed the course of the Stead trial at London, will have been interested in that feature of it relating to the physical examination made of Eliza Armstrong, the young girl alleged to have been abducted for immoral purposes. This examination was made by Dr. Heywood Smith, under the belief that Mr. Stead, who had applied to him, was the guardian of the child. The developments of the trial were such that the Royal College of Physicians considered it proper to examine into the matter and see if the conduct of Dr. Smith was improper or not. The committee appointed for this purpose reported that his conduct had been unprofessional, and that he deserved a reprimand. In carrying out this decision, the President of the Royal College of Physicians said: "Speaking generally and without regard to this special case, or to cases involving medico-legal questions or about to come before courts of law, it is, in the opinion of the college, a grave professional and moral offence for any physician to examine physicially a young girl, even at the request of a parent, without first having satisfied himself that some decided medical good is likely to accrue to the patient from the examination, and also without having first explained to the parent or legal guardian of the girl the inadvisability of such examinations in general, and the special objections that exist to their being made. Moreover, the college feels that a young girl should on no consideration be examined excepting in the presence of a matron of mature age, and so far as the physician can know of good moral character. By failing to conform to rules that should regulate professional conduct, rules founded on concern for the public good and on sound moral principles, you would, had not the college taken its present action, have brought dishonor on the college of which you are a member, and discredit on the profession to which you belong. Having regard, however, to the motives that influenced you in your actions, to the fact that you were misled by others, to your full acknowledgment of the wrong you did, and to the promise you have given to the college in reference to your future conduct, the college has determined not to erase your name from the list of its members, but has desired me as their mouthpiece to reprimand you, and to admonish you that any deviation in the future from strictly honorable professional conduct will be followed by the severest punishment the college can legally inflict." The dangers from the physical examination of females are not alone noticeable in cases similar to those mentioned by the President of the Royal College of Physicians, but any private examination of the kind makes it possible to blackmail a physician, and the only safe course is always to require the presence of a third person. This was clearly shown in the trial recently concluded at Leeds, England, of Dr. Heath, who was charged with an assault upon a female patient. It was shown, however, that she was subject to attacks of hysteria, and the jury decided that the case was one of hallucination.

Damages Sought for Delay in Transporting a Dead Body.

A curious suit has been brought in Illinois against the Chicago, St. Louis and Pittsburgh Railway, and the Pullman Palace Car Company, to recover $50,000. It is brought by George Brown, an attorney, of Decatur, Ill., whose wife died in May last, and whose remains were sent to Zanesville, Ohio, for interment. A party of five, besides Mr. Brown, went with the body, but by some mistake the body was taken from the train at Indianapolis, while the passengers went through to Columbus, Ohio. The body remained at Indianapolis twelve hours, and when it finally arrived at Zanesville it was decomposed. The time of burial had to be changed, and the friends were unable to look at the body. For these reasons the suit to recover damages was brought. The railroad in its answer denies any negligence, and claims that it did all that could be required of it.

Circumstantial Evidence.

The following interesting case was recently tried in Paris, and forms a notable instance of the incorrectness of seemingly conclusive circumstantial evidence. A woman was put on trial for strangling her baby, and at the preliminary examination she confessed the

crime. At the trial, medical evidence was heard, and the doctor told the judge that he did not believe the woman was the real culprit. The finger-marks were fresh on the victim's throat when he made the examination, and the marks were singular. He examined the woman's hands, and found her fingers long, slender, and well-shaped; but the marks were of a short-fingered hand, stumpy and misshapen, and one of the fingers—the first—was abnormally short. On this the prisoner burst into tears, and said she was fond of the child, had not destroyed it, and mentioned in her excitement the real culprit. He was a man of the better class of life, with whom she had lived as a domestic servant. His arrest followed, and the doctor pointed out that the prisoner's hands were formed as he had described, and, moreover, that the first finger was without a nail, and almost deficient of a joint. On this evidence the jury convicted the man.

International Medical Congress.

At a regular meeting of the Montgomery County Medical Society (Pa.), September 23, 1885, the following preamble and resolution were adopted, with but one dissenting vote:

WHEREAS, The American Medical Congress has invited the Triennial Congress which convened in Vienna in 1884 to hold its next meeting in this country in 1887, which invitation was accepted; and,

WHEREAS, Certain eminent and worthy members of our profession in some of our large cities are dissatisfied with the arrangements made by the Association for the government and management of the Congress and its personnel, and by their hostility are fomenting discord among the members of the profession in this country, which may imperil the success of the Congress; therefore,

Resolved, That we approve the action of the American Medical Association on this subject at St. Louis, in 1884, and at its meeting in 1885, and also the recent action of its committee on September 3, in New York, and that as individuals and as members of the Montgomery County Medical Society, we will do what lies in our power to aid the American Medical Association in its efforts to make the Triennial Congress a success.

C. Z. WEBER, M. D.,
Recording Secretary.

The Hammersly Will Contest.

The will contests involving the question of insanity and undue influence, which vex the courts constantly, have rarely been so entertaining to the public as that in which the mental capacity of Mr. Louis C. Hammersly, of New York, was questioned. The estate was a large one, and naturally the strife over it was bitter and long, but this was not the point that the general public was most interested in. An old servant named Becky Jones was called to testify against the mental powers of her employer, but she absolutely refused to say a word, and the court and lawyers were unable to induce her to change her mind. Imprisonment for nearly a year had no more effect upon her than threats or persuasions. The case could not wait for her, however, and it went on, having only very recently been decided. Becky Jones was discharged awhile since, but she kept her word, and said not a word.

The Plymouth Epidemic in Court.

The remarkable typhoid epidemic which raged so fiercely at Plymouth, Pa., last spring and summer, is to find its way into the courts. A short time since some fourteen suits were begun in the Court of Common Pleas of Luzerne county, against the Plymouth Water Company, by the relatives of some of the victims of the epidemic. About 100 in all died from the disease, and the plaintiffs in these suits charge that the epidemic was caused by the failure of the company to provide pure water for the people of the town.

Damages to the extent of $10,000 are claimed in each case, and it is expected that other suits will follow. The water company will fight the cases bitterly, and will endeavor to show that the typhoid fever originated not in the water, but from the bad sanitary condition of the town.

Correction.

EDS. MED. AND SURG. REPORTER:

In the report of my case of "Labor Complicated by Placenta Prævia and an Intramural Fibroid Tumor," in the REPORTER of February 13, I am by some inadvertence of the reporter made to say a very stupid thing, viz: "that it is an unusual circumstance for a woman over forty years of age to suffer from a fibroid tumor." The sentence should read as follows: "The fact that a woman over forty years of age, suffering from a fibroid tumor filling up the greater portion of the uterus, *should conceive*, is in itself, I think, an unusual circumstance."

This is a very small matter, but I shall be

much obliged if you will correct it in your next issue. JOHN MORRIS, M. D.
Baltimore, Md.

Oleomargarine.

The oleomargarine question is one of the most important, relating to the adulteration of food products, and the efforts to prevent its manufacture and sale are giving the courts of the different States, and particularly of New York, considerable business. Since the Court of Appeals in that State decided that the manufacture could not be absolutely prohibited, a law has been passed making the offering for sale of oleomargarine as butter a penal offense, no matter whether the seller had knowledge of it or not. A test case involving this point has just been tried in New York city, and it will be taken to the Court of Appeals for final settlement.

Medical Society of the State of Pennsylvania.

This body will hold its thirty-seventh annual session in the city of Williamsport, June 2, 3, and 4. The programme of the entire session is required to be distributed at least one month before the meeting, therefore all who desire to present papers are requested to forward the title and a brief abstract of the subject at an early day. No voluntary paper is allowed to occupy more than twenty minutes in reading.

DR. T. H. HELLSBY, Williamsport,
Chairman of Com. of Arrangements.
W. B. ATKINSON,
Permanent Secretary.

Information from Pasteur.

M. Pasteur, in reply to a letter asking advice as to the case of Councilman Denizot, of Cape May, N. J., who was bitten while separating two fighting dogs on New Year's day, writes:

"When a dog is enraged, he dies in the madness in a few days. So if the dog of which you speak in your letter of January 3 lives yet, it is because he was not enraged, and the person whom he bit has nothing to fear. Let him take care of his bite as an ordinary wound."

Druggists to be Warned.

At the meeting of the New York State Board of Health, February 3, the chemists from different parts of the State, appointed to investigate the matter, reported that many druggists were selling certain drugs below the regular scale of purity. They were ordered to inform such druggists that by selling drugs below the standard of purity they made themselves amenable to the laws.

Personal.

Dr. J. C. Richards, Phillipsburg, Pa., desires the present address of Dr. W. H. H. Gibbons, who practiced at Glen Hope, Pa., about 1859.

Items.

—Cinchona cultivation has been commenced in Guatemala. The plantations are at an altitude of 4,000 to 5,000 feet.

—The cinchona trees of all ages now under cultivation in the Wynaad district (S. W. India) number 5,000,000.

—The first course of medical lectures given in what is now the United States was delivered by Dr. Cadwallader, at Philadelphia, in 1751.

—By ministerial decree the importation into Roumania of patent medicines and proprietary articles, with the exception of some specially declared exempt, has been prohibited from January 15, 1886.

—A Los Angeles accoucheur was about to to take the placenta with him for some scientific purpose when the new-made mother cried: "O, doctor! for God's sake leave that and let the nurse burn it, or I shall have terrible after-pains." The doctor left it, the nurse burned it, the woman had severe pains, and—was the M. D. sorry for her?

—There appears to be much room for the sanitarian in the cities of Japan. We learn from the Transactions of the Society for the Advancement of Medical Science in Japan, that in a city with a population of a million and a quarter the death-rate amounts to 56 per 1,000.

—Servant (to drug clerk): "Oi want twinty-foive cints' worth of powder." Drug clerk: "What kind of powder—face powder?" Servant: "Oi don't know, sorr." Drug clerk: "Who is it for?" Servant: "It's for Mrs. Hendricks, the lady what kapes the boordin' house beyant the corner." Drug clerk: "Oh, yes! I used to board with Mrs. Hendricks myself. She wants insect-powder."

—Dr. Govan stated at the New York State Medical Association that he had used aniline oil for the purpose of producing

local anæsthesia when laying open felons and performing other minor operations. There was absolutely no pain, even in cutting down to the bone, when the finger had first been dipped for a short time in oil.

—Hydriodic acid is growing in favor in cases of spasmodic asthma. It is given as a syrup in doses of from ʒss to ʒj. The syrup is much more stable than syrup ferri iod., and contains one per cent. of absolutely pure hydriodic acid. A large number of patients state that doses of 20 grains of the syrup afforded them more relief than any other remedy for asthma, surpassing even grindelia and the much-vaunted mixture of ext. grindelia and syrup of garlic.

—Gelatin bougies and suppositories are made of firmer consistency (Rundschau, No. 45) by the addition of acacia, without, it is claimed, interfering with their solubility. The proportion is about as follows: Gelatin, 5 ounces; acacia, 5 ounces; glycerin, 12½ ounces; and water sufficient to make 25 ounces. The gelatin and acacia may be dissolved in water separately, then mixed with the glycerin and evaporated to the proper consistence.

—In a recent number of *Brain*, Professor Dreschfeld has further interesting observations on alcoholic paralysis. He has found that Magnus Huss, who is generally credited with having been the first to describe a paralytic form of chronic alcoholism, was preceded by thirty years by Dr. James Jackson in the United States. The latter wrote in 1822. Dr. Dreschfeld has clinically divided this article into two groups, alcoholic ataxia and alcoholic paralysis—a classification followed by Lowenfeld, Moëli, Schulz, and Krück. Alcoholic paralysis is a multiple peripheric neuritis.

QUERIES AND REPLIES.

Papayotin.

Dr. Lawrence Wolff, of Philadelphia, thus kindly answers our numerous inquiries in reference to papayotin:

Moncorvo, of Rio de Janeiro, first called attention of the medical world in 1879 to the peptonizing power of the milky juice of the unripe fruit of the melon tree, or papaw, the carica papaya L., carica vulgaris D. C., of the natural order of papayaceæ, habitat Brazil and the tropical countries of South America. It had been long ago employed by the natives of these countries as a vermifuge, but large doses were cautioned against as possessing an irritant and corrosive action on the intestinal mucous membranes.

The early reports of Moncorvo regarding the digestive principle of the juice, obtained by precipitating it with alcohol as an amorphous greenish substance, which he termed "caricin," were soon confirmed by Bonduit and Wurtz. The latter of these separated from the papaw juice a digestive principle similar to pepsin in its action, which he called "papain," and which Balke named "papayacin." More recently, Zeckolt, of Rio de Janeiro, separated both from the milk of the fruit as well as from the leaves, the digestive principle, "papayotin," which is the one now generally employed. Zeckolt stated that the fruit yielded 7.848 per cent., and the leaves 0.119 per cent., but that nevertheless the leaves could be worked to better advantage. The inference is that the "papayotin" of the market is largely obtained from the leaves, although the product from this source appears to leave less digestive power than that of the fruit.

The juice of the unripe fruit is obtained by incisions into the rind. Incisions into the bark of the tree, and the wounds from tearing off leaves or branches, also yield digestive juice. It is of neutral or slightly acid reaction, of bitter taste, and gelatinizes when mixed with about three times its volume of water. When sun dried, it is a yellow plastic substance, that can can be kept for some time without impairing its virtues. It is said that the juice of other species of papaya leave similar peptonizing properties to that of the papaw.

The papaw juice is a decided peptonizing agent, dissolving muscular fiber, gluten, croup membranes, etc., coagulating the casein of milk, and redissolving the coagulated casein at the temperature of the body. The solutions so made possess the characteristics of peptones. The irritant action of the juice is not apparent in the isolated digestive principle. According to Wurtz, papain digests 1,000 times its weight of moist fibrin. Experiments made with some specimens of papayotin seem not to confirm the great digestive power of this agent, while others again fully demonstrate it. The advantages of the digestive principle of papaw juice over pepsin is that it will act either in neutral or alkaline solutions.

According to Grelletz, one decigram of papain corresponds to about one grain of the recent juice, and is sufficient to dissolve about 50 grains of meat. Very excellent reports have been made of the use of papain for the dyspeptic symptoms and gastro-intestinal irritation of cholera infantum, while recently the application of a solution of papayotin of one part in twenty parts of water or glycerin has been recommended to dissolve the membranes of pharyngeal diphtheria. Samples of excellent papayotin have been sent to the writer by Messrs. Parke, Davis & Co., which had been imported by them.

Terebene and its Derivatives.

Having been asked by several correspondents for some information about Terebene, we will answer all with the following annotation from the *Brit. Med. Jour.*, Feb. 6:

"This substance, which has lately come into prominence as a therapeutic agent, was first manufactured many years ago. As far back as 1873, M. Riban read a series of papers before the Pharmaceutical Society of Paris on this and similar substances. By acting on twenty parts of well-rectified oil of turpentine, boiling at 160° C. (320° Fahr.), with one part of concentrated sulphuric acid, a product is obtained by distillation at 250° C. (482° Fahr.), which is a mixture of terebene and cymene. The liquid so prepared is treated several times with caustic potash, in order to eliminate any acid products. By fractional distillation the following products are obtained: 1. Terebene, with a boiling point of 156° C. (312.8° Fah.); 2, cymene, boiling at 170° C. (338° Fahr.); 3, a camphoraceous substance, which distils over at 200° C. (392° Fahr.); and 4, colophene and several higher compounds. Pure terebene (C_{10} H_{16}) is a colorless mobile liquid, with a faint odor, of specific gravity of .877 to 1,000. Treated with dry hydrochloric acid gas, a crystalline mass forms, which consists of hydrochlorate of terbene (C_{10} H_{10} HCL), commonly known as turpentine camphor. This substance, when the uncrystallized liquid has been expressed, consists of white friable crystals, which can be reduced to a powder without much difficulty, which distinguishes it from its isomeric hydrochlorate of turpentine, which is soft and pasty. Indeed, it was in seeking the causes of this divergence of qualities that M. Riban, who could not attribute it to the presence of impurities, was enabled to discover one of the most remarkable properties of the hydrochlorate of terebene, namely, its separation into camphene and hydrochloric acid, under the influence of cold, and its rapid resolution into the same substance by the action of cold water, which takes up the acid. The preparation of the hydrochlorate is by no means easy, if the compound be desired in a state of purity, and it can only be effected by means of special precautions and delicate manipulation. The raw material is dissolved in rectified spirit, at a temperature which must not exceed 55° to 60° C., as otherwise the major part of the mass may be converted into liquid products. On cooling the solution, large flakes of the hydrochlorate, now rather poorer in chlorine, are deposited. These crystals, deprived of their alcohol in a dry cold atmosphere, are then submitted to the action of hydrochloric acid gas. The crystals are melted in presence of this gas, at a temperature of 130°, and allowed to cool gradually. The hydrochlorate of terebenthene is obtained by acting on the oil of turpentine with hydrochloric acid, and this is isomeric with the analogous compound of terebene. Other isomers exist, as for instance the hydrochlorate of camphene, as well as the hydrochloric ether of natural or artificial borneol. Terebenthene was separated in a state of purity by M. Berthelot, by distilling the crude material *in vacuo*, after neutralization of the acid impurities."

ENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle, pleasantly flavored. Retail $1.00. All of it pure pepsin.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

SUDDEN EXTENSIVE FATAL CEREBRAL HEMORRHAGE — REPEATED ATTACKS OF CEREBRAL HEMORRHAGE, WITH LOSS OF CONSCIOUSNESS — PLEURISY, WITH ANOMALOUS SYMPTOMS, SUGGESTING TYPHOID FEVER.*

BY WILLIAM PEPPER, M. D., LL. D.,

Provost of, and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania.

Reported by William H. Morrison, M. D.

Gentlemen: Before referring to the case before you, I wish to describe a case which I saw in consultation last night. The patient was a vigorous, strong man, about fifty years of age, in active medical practice. About three o'clock yesterday afternoon he was visiting a patient and arose to leave the room, when he complained of a severe pain in the head and almost immediately fell to the floor, profoundly unconscious, with stertorous breathing. Physicians were sent for, the first arriving in thirty minutes. He found the patient with a purple face, eyes congested, throbbing action of the vessels of the neck, rapid, strong pulse, and absolutely unconscious. There had been vomiting of what had been eaten. The entire muscular system was completely relaxed. The pupils were contracted to small points and were entirely irresponsive to light. The conjunctivæ were completely insensible to touch. No reflex movements of any kind could be elicited. When first seen, about a quart of blood was taken from the arm and hypodermics of ergotine administered. The treatment was entirely without effect.

I was called about half past nine at night, six hours after the occurrence of the apoplexy. There had evidently been a central ventricular effusion of large size. It is not impossible that there had been an aneurism within the brain, which had burst. The effusion was evidently central, for the whole muscular system was relaxed. There had not been a movement on either side of the body since the occurrence of the attack. The reflexes on both sides had also entirely disappeared. There probably was pressure on the corpora quadrigemina and irritation of the roots of the optic nerve because of the contraction of the pupils. There was no deviation of the head or eyes. It is sometimes observed in cases of apoplexy that the head or eyes are turned towards the affected side. The breathing was very stertorous, the sounds filling the entire house. The pulse was very rapid and varied much in frequency, varying in five minutes from 150 per minute to 180. Death was imminent, and I remained until it took place a short time later.

That was an instance of frightfully large hemorrhage, tearing out the central portion of the brain, and stopping all its functions. I think that it was perfectly right to bleed the man as was done. It did no harm, and on the other hand, if the hemorrhage had been of moderate amount and attended with intense engorgement of the brain, the removal of blood might have affected the surrounding engorgement, and lessened the amount of hemorrhage and the damage to surrounding tissue. This treatment having been tried without appreciable improvement,

* A clinical lecture delivered at the Hospital of the University of Pennsylvania.

further venesection would not have been desirable. These are cases in which nothing can be done.

Repeated Attacks of Cerebral Hemorrhage, without Loss of Consciousness.

In the man before you we have a very different history. He is 69 years of age, and has been an exceptionally strong and hearty man. He has committed no excesses. There is no venereal history. His father died of apoplexy, and he has lost a brother and a sister from the same cause. Until two years ago, his bodily health was good, and his mental powers apparently well preserved. At this time, without warning and without apparent cause, he one day suddenly fell to the floor, and on being helped to his feet he found that he had lost power in the left side, not absolutely, but in a decided degree. There was marked left-sided hemiplegia. He does not remember whether or not there was any loss of sensation. There was no loss of consciousness. He felt the attack come on, he knew when he fell, and knew when he was lifted up. There were no brain symptoms at all, and in four or five days the loss of power almost entirely disappeared. There were no twitchings or involuntary movements. During the next two years he had two similar attacks, and the left side was again affected; although power returned, the left side remained a little weaker after each attack, The speech has not been affected in either of these attacks. The muscles of the face, however, have been paralyzed with each attack, each time being drawn to the right. This passed away after a short time.

Eight weeks ago he had a stroke, which left him in the present condition. There was no loss of consciousness, but total loss of power in the left side. His speech was affected, owing to the paralysis of the tongue and muscles of the face. During the four months preceding the last attack, he had experienced occasional attacks of dizziness, in which objects seemed to float around him. Through all these attacks, memory, intellect, and the special senses were entirely unaffected.

On admission the following was noted: the mental faculties are normal; there is no trouble with the bowels or bladder; the heart is only slightly enlarged; the first sound is somewhat heaving and prolonged, and the second sound accentuated; his arteries are tortuous and atheromatous; there is distinct arcus senilis; there is very little power in the muscles of the left side; the face is drawn to the right side, and the tongue is protruded to the left side; the reactions to faradization are diminished in the paralyzed muscles, and the galvanic reactions are much impaired; his sight has been failing a little, as would be expected at this age; hearing is normal; the speech is affected, but there is no aphasia; the pupils are equal and contract to light; the urine contains neither albumen, sugar, nor tube-casts. Such was his condition when admitted.

Let us note a few of the important features in this case. There have been four successive attacks, the symptoms of which seem to make it clear that there has been hemorrhage into the brain on the right side in the region of the corpus striatum, probably in the lenticular nucleus. Each attack produced complete paralysis of the left side, without any involvement of sensation and no aphasia. It is to be noted that in these attacks there has been a singular absence of loss of consciousness. In some cases where loss of consciousness does not accompany hemorrhage into the brain it is explained by the smallness of the hemorrhage, and possibly by the fact that it is not a true hemorrhage, but only a sudden congestion. In congestive apoplectiform attacks, the patient is suddenly seized with weakness of one side, sometimes with and sometimes without loss of consciousness. There may be capillary hemorrhage without unconsciousness.

Another reason why loss of consciousness is sometimes absent is because the irritability of the brain tissue is impaired, from beginning softening, and in such cases even a considerable hemorrhage may occur without loss of consciousness. Loss of consciousness is, therefore, not always a favorable indication. It is sometimes unfavorable, as indicating that the brain tissue has undergone degeneration. The prognosis of many cases of apoplexy without loss of consciousness is less favorable than that of cases where there has been loss of consciousness of moderate duration. Such patients are very apt to present progressive enfeeblement, repeated attacks, and the paralysis is apt to remain.

This patient, as I have said, has had four attacks, without loss of consciousness, and with complete paralysis; and with this we have the very interesting fact that this paralysis has passed away very rapidly. He has lately been more liable to these spells, and they are becoming worse. The last attack, although much worse than the others, has been followed by a rapidity of improvement which is exceptional. While the history and the condition of total paralysis when admitted indicated that the man was

paralyzed for life, yet we find that this left arm, which was absolutely dead, has rapidly regained power, and he is able to move the hand and to bend the arm. Power is also returning in the leg. The face, although drawn a little to the right, is improving.

I have said that this history indicates the occurrence of hemorrhages: at the same time it is proper to consider whether there is any other condition which could explain the occurrence of these spells. They have certainly not been the result of simple congestion. They might have resulted from small emboli lodging in the right middle cerebral artery, blocking up the small vessels and cutting off the circulation from a small area, and producing temporary paralysis. Under such circumstances there is scarcely as much paralysis as this man has presented. There is here atheroma which would explain roughness of the lining of the vessels, but there is no evidence of valvular disease of the heart with vegetations, portions of which being broken off might be forced into the circulation, causing emboli. In cerebral embolism there is nearly always valvular disease of the heart. The degree of atheroma is not sufficient to make us suspect that there are bony plates in the lining of the vessels, with shreds of fibrin which might be carried into the circulation.

The fact that there has been recurrence of the attacks, which is rare in embolism, and the absence of valvular disease of the heart, may be taken as showing that these attacks were due to cerebral hemorrhage.

In a case of this kind it is impossible to make a positive prognosis. We can say that this man is more liable to subsequent attacks. Some patients may have a number of spells before the brain passes into such a state of softening that at last one proves fatal.

The treatment of this case has consisted in absolute rest and careful regulation of the diet. Electricity has been used to the paralyzed muscles. As there has been no indication for internal treatment, none has been used. When the faradaic current was first employed the response was very imperfect. This was when the man was admitted two weeks ago. When we consider that the man had been paralyzed for six weeks, and the muscles were gaining strength very slowly, and that in two weeks with faradization they have gained rapidly, it is proof that this electrical treatment has been of service in this case. So many of these cases are almost necessarily fatal, from the character of the lesion, that we sometimes lose sight of the fact that in suitable cases electricity is a remedy of decided value. In the present case the indications for it were perfectly clear. There was no evidence of irritation of the brain, which is often a contra-indication for electricity in hemiplegia. There was no pain, no elevation of temperature, no disposition to rigidity or to contraction of the paralyzed muscles. Electricity was thus perfectly proper, and the form used was that which caused the greatest response in the muscles. The galvanic current, slowly interrupted, scarcely caused any movement. The faradaic current gave a response, and the muscles have been faradized every day with the result which we have seen. Although the improvement in this case is very satisfactory, yet I consider the man in a state of great danger.

Pleurisy, with Symptoms Suggesting Typhoid Fever.

This patient has been a source of some little anxiety and uncertainty in regard to the nature of his case. He came into the hospital five days ago. He is 26 years of age, has a healthy occupation, and has no family history bearing upon the present illness. He has been dissipated and has drunk to excess. Four weeks ago he had gonorrhœa, and was treated by a druggist. Twelve days ago he began to feel weak, dull, and dizzy. At the same time he had headache, poor appetite, and dryness of the mouth. Then he had a stitch in the side which was made worse by movement and by breathing. This has remained. Then he had a little bleeding from the nose. There has been no chill, but feverish feelings. The bowels have been regular, being open once a day or once every other day.

On admission five days ago, his face was flushed and his hands tremulous. The movement on breathing was more marked on the right side, the left side not moving, chiefly on account of pain. The heart was in the normal position. There was a little pleurisy with friction sounds, but no effusion. The abdomen was distended, and there was some tenderness on the right side. The tongue was coated. The temperature on admission was 102.5°. The same night it was 104.2°. The following night, 104.6°. The pulse has never been above 105 per minute. The man's condition has gradually improved. The temperature has varied between 101° in the morning and 104° in the evening. There has been marked fluctuation in the temperature. It has been as low as normal in the morning and the same evening reached 104°. This morning it was 100°.

The pain in the left chest has continued, but there has been no pleural effusion—simply a little dry pleurisy with considerable muscular pain. There is a little cough with expectoration, but no pulmonary lesion. There has been epistaxis, but no diarrhœa. At no time have I been able to find any eruption on the abdomen. The tenderness in the right iliac fossa has continued. Two days ago the patient had a chill about 1:30 p. m. Yesterday, for the first time, some effusion was discovered in the left pleural sac.

The urine has been examined and found free from sugar and albumen.

We have discussed the question whether or not this man has typhoid fever. There are certain symptoms pointing in that direction. The type of fever, the epistaxis, the muscular weakness, the slight cough are such as are found in a mild case of typhoid fever. The case is, however, wanting in some characteristic features. One of these is the eruption of typhoid fever. This is absent. There has been no tendency to looseness of the bowels. We know perfectly well that while typhoid fever often presents an eruption, it often runs its course without any eruption. Again, we often find in mild typhoid fever in this region, that the bowels are quiet and often constipated from the beginning to the end of the attack.

Another point of interest is that ever since admission, and judging from his statement, throughout his entire sickness, the man has had a pleuritic pain in the left chest. Friction sounds have been present ever since he came under observation, and now there is the formation of effusion. This is a complication which does not usually accompany typhoid fever.

This local inflammation might be sufficient to explain the fever which has been present, and the question has been to determine whether this fever and anomalous symptoms were due to typhoid fever, or to be explained by the local pleurisy which might reasonably be expected to keep up some fever, particularly as the existence of gonorrhœa disposes the system to inflammatory conditions.

I would add that there is no enlargement of the spleen, which is another point against typhoid fever.

I do not dwell much on the absence of delirium and nervous symptoms, because in mild typhoid cases these also may be absent.

This case is certainly wanting in some of the characteristic symptoms of typhoid fever, and my judgment is that the man has not had typhoid fever, but simply a symptomatic fever connected with the subacute pleurisy. Still the case is one in which it is impossible to be absolutely certain, and I have, therefore, given him the benefit of the doubt and treated him as though he had typhoid fever. I have kept him in bed, giving him a liquid diet and the hygienic care which would be suitable for a case of typhoid fever. Internally, we have given iodide and acetate of potassium for the relief of the local inflammation. I shall order a blister three inches square applied to the affected side.

Communications.

TRACHEOTOMY.*

A Report of Nine Cases.

BY JOSEPH RANSOHOFF, M. D., F. R. C. S. ENG.,

Professor of Anatomy, Medical College of Ohio, Cincinnati.

Case 1. Miss L. K.. æt. 22, generally troubled with sore throat, November 17, diagnosed diphtheritis. Dr. B. Tauber was called in consultation. She was seized with suffocative attacks which necessitated tracheotomy. The inferior operation was made. Extensive membranes removed. Relief very decided, but continues only three hours. In the afternoon practiced aspiration of the bronchi and removed some muco-purulent fluid. Death from œdema pulmonum ten hours after the operation.

Case 2. Z. G., female, æt. 5 years, called by Drs. Krouse and Wilfert. Patient has been sick for ten days with diphtheria. Examination of the throat revealed thick and extensive patches on both tonsils and uvula. Cervical glands enlarged and painful. Patient restless, pale, and cyanotic; face covered with clammy perspiration. Temperature slightly subnormal. Respirations 40. Inspiratory depression of jugulum and epigastrium. Pulse 144 and scarcely perceptible. Croupous cough and aphonia very pronounced. The surroundings of the patient being ill-suited to the after-treatment, she was conveyed to the Good Samaritan Hospital, where on the 20th of March the trachea was opened below the thyroid isthmus. The use of the grooved director in tearing through the soft parts caused the laceration of a large vein, from which the hemorrhage was excessive. It being impossible to find and ligate the ruptured vein, a

*Read before the Cincinnati Academy of Medicine, January 4, 1886. (Abstract.)

hemostatic forceps was applied and retained in place for twenty-four hours. After the trachea was opened, large shreds of membrane were coughed up and others removed with the feather, both from below and above the tracheal aperture. After the operation, a rubber canula was inserted and the temperature of the room kept at ninety degrees, and the air moistened. The wound was covered with carbolized gauze, and continuous inhalations of bicarbonate of soda given. On the second day after the operation the temperature rose and the pulse became frequent, and continued so for nearly two weeks. Profuse hemorrhage occurred from the wound on the fourth day. Canula removed on the fifth day. Patient discharged on the twenty-sixth day in perfect health and with normal voice.

Case 3. J. R., æt. 13, was called in consultation by Dr. Forcheimmer. The sister of the patient first contracted diphtheria of the fauces, which was followed by diphtheritic paralysis. The little patient himself was ill with the disease for one week prior to the operation. Saw him twice in consultation on the 7th of May. Morning temperature 103°; evening, 104°. Pulse 150 to 160. Diphtheritic deposits on left tonsil and uvula, and absence of voice, were noted. On the night of May 7, symptoms of asphyxia supervened. Temperature 102°. Pulse 180. Respiration sawing and labored. Fingers cyanotic and cold, and child semi-comatose. Tracheotomy was performed below the isthmus without anæsthesia on the afternoon of May 8. No hemorrhage. Shreds of membrane were removed, and the tube, a hard rubber one, inserted. Dyspnœa removed at once. Patient drank a glass of milk immediately after being removed from the table. Treatment as in the first case. Tube removed on the fourth day. Recovery quite tedious on account of the supervention of malaria.

Case 4. D. R., female, æt. 9 years, attacked with sore throat July 23. Complained of difficulty in deglutition and occasional chills. I saw the patient first on the 26th of July, and found diphtheritic patches on both tonsils and uvula. Swallowing somewhat painful. Glands at the angle of the jaw tender and enlarged. Ordered lime-water inhalations and quinia and alcoholic stimulants internally. On the 29th slight hoarseness supervened, which on the 30th had changed to complete aphonia. Frequent attacks of coughing and of laryngeal spasms. Dyspnœa very marked, and attended by depression of jugulum and epigastrium. An emetic of the subsulphate of mercury gave only temporary relief. Dr. Nickles at this time saw the case in consultation. Tracheotomy was performed below the thyroid isthmus on the 31st. The opening of the trachea was somewhat enlarged by the enlarged thyroid. Extensive membranous shreds were expectorated and removed by the feather before the hard rubber tube was inserted. After treatment, as in previous cases, the patient revived quickly after the operation, and the painful dyspnœa was relieved. The respiratory impediment, which still continued, was doubtless due to implication of the fine bronchial tubes. Death 40 hours after the operation.

Case 5. S. K., æt. 2; called in consultation by Drs. Reamy and G. S. Mitchell early in November. Patient had an attack of measles, from which he recovered slowly. Toward the end of the month, throat symptoms supervened, with elevation of temperature and great loss of strength. On the 6th of December, dyspnœa intervened and some loss of voice was observed. On the 7th, the patient fell into a semi-comatose condition, from which he could be aroused only with considerable effort. Early on the 8th, the little patient was pale, lips bluish, perspiration clammy, and the feet and hands cold. He was comatose from carbonic acid intoxication. Breathing very labored and noisy, with sinking in of the epigastrium and total loss of voice when coughing or crying. The subsulphate of mercury had been twice given and produced emesis, but without permanent benefit. Infra-thyroid tracheotomy was made as a last resort and without anæsthesia. The operation partially relieved the dyspnœa, but the patient did not regain consciousness. Death twenty-four hours after the operation. Ante-mortem temperature 106°.

Case 6. M. S., male, æt. 5; called in consultation by Dr. C. D. Palmer. Brother affected with scarlatinal and slight diphtheritic sore throat. Developed a scarlatinal eruption on the 23d of January, and on the following day diphtheritic patches appeared on the tonsils, which were always enlarged. His temperature at this time was 104°; pulse 120. Symptoms of laryngeal occlusion developed on the 26th. The local treatment had consisted of the application of the perchloride of iron. Was called to see the patient at 12:30 a. m. on the 28th of January. Although he occupied a back room in the upper part of the house, his noisy breathing was audible below in the front hall. The patient was sitting in bed, with face pale, and

covered with perspiration; lips purple and fingers tumefied. He frequently cried, "I am choking, I am choking!" Pulse 160 and feeble. Temperature 102°. Respiration greatly impeded. Inspiration is long and labored; expiration noisy and prolonged, and voice very husky. Occasionally there is a low barking cough. The tonsils almost touch each other. They and the soft palate are completely covered by a thick, greyish membrane, which is firmly attached. Tracheotomy below the isthmus under partial anæsthesia. Large quantities of mucus and membranous shreds removed through the aperture. Relief to respiration immediate. Local treatment as in the previous cases, with the addition to the topical applications of the perchloride of iron to the throat. On the fourth day severe hemorrhage from the tracheal wound, which we believe to result in separation of the membranes. The tube was removed on the sixth day. Recovery rapid and uninterrupted.

Case 7. J. L., æt. 2 years; called by Dr. Good, has been ill for four days with diphtheria of nose and pharynx. On the fifth day symptoms of laryngeal stenosis supervened, when a consultation with tracheotomy in view was demanded by the physician in charge. At this time the patient was greatly asphyxiated, and the constitutional depression very marked. The pulse 180 and very feeble. Profuse deposits on the tonsils and uvula and very offensive discharge from the nose. The respirations were very rapid, but the laryngeal noises precluded the possibility of an examination of the chest. Tracheotomy below the thyroid was made, but no membrane was removed. The relief to the dyspnœa was very marked, but did not continue for more than twenty-four hours. Death from catarrhal pneumonia sixty-two hours after the operation.

Case 8. H. S., æt. one year; called by Drs. Ayres and Richard. The child had been sick for three days before medical aid was solicited. When first seen, presented diphtheritic deposits on left tonsil and uvula. Pulse very rapid and feeble. Temperature not much elevated, but irregular. When seen in consultation, it was almost pulseless. Respiration very labored and noisy, with sinking in of jugulum and epigastrium. Patient in a condition of sopor and unable to recogize its mother. September 25, tracheotomy inferior was made without anæsthesia. The asphxia was completely relieved. The child returned to consciousness and nursed completely, but sudden restlessness supervened six hours after the operation, and this was attended by a temperature of 106 degrees. Death ten hours after the operation.

Case 9. A. F., æt. 3½ years, previously quite well, was taken ill suddenly November 10. He had gone to bed feeling quite well, and wakened in the morning with considerable pain in the throat. Difficulty of swallowing, fever, and some prostration. His sister had suffered the week previous to this attack from an epidemic of follicular tonsillitis, which subsided completely after three or four days. On the 11th of November a few white spots appeared on each tonsil, and there began to appear over the body an ill-defined scarlatinal eruption, which was more decided on the following day. On the 12th, the white coating extended over the entire mucous lining. The voice was clear, and the child's manner as cheerful and lively as usual. At noon a sudden summons came. All had changed. The child was cyanosed; there was a marked lividity about the face; the voice was almost entirely absent; breathing very labored and increased in frequency, and there were several attacks of dyspnœa, in which it seemed minutes before he could get his breath. The voice was hoarse; the cough croupy. Tracheotomy was performed and afforded prompt relief. Twice in the first four days the child pulled the tube from the trachea. The condition was extremely precarious. The temperature fluctuated between 102° and 103½° in the rectum. The pulse was seldom less than 120, often above 130; respirations as frequent as 56 per minute. The tube was removed on the tenth day, the wound granulating quickly, and complete closure had already taken place eight days after its withdrawal. The child is now as well as ever, with the exception of a slight hoarseness after free use of the voice.

NONCONFORMITY TO TYPE IN FEVER, ESPECIALLY IN TYPHOID FEVER.

BY E. T. BLACKWELL, M. D.,
Of Cedarville, N. J.

The physician who has stored his mind with classical descriptions of disease, often finds it difficult to harmonize the affections presented to him with any recorded type or species. Especially is this true of fevers, which present numberless differences, though all, perhaps, referable to known varieties of a given type, if studied with proper diligence and with a true determination to trace each specimen to its legitimate position.

It is well for us to dismiss the idea that we can, in any given case of fever, refer it at once and unfailingly to its proper nosological place. We cannot be sure that the type which it bears at its outset will be continued to its end, and that it may not, in a few days, settle down to a form different from what at first appeared likely. That our nomenclature is often misleading is a matter of common observation.

The person who is testing the several symptoms of fever in a given case often finds one or more factors wanting to complete a perfect formula; but in a series, plainly derivable from the same source, or propagated by the same special poison, the "missing links" may be gathered from the different specimens so as to construct a typical form. In this way the hebetude, so characteristic in well-marked cases, may be scarcely noticeable in the milder form, or be quite absent; the color may not be so affected as to excite attention; there may not be epistaxis; the bowels may be unaffected; tympany may be moderate, and gurgling may fail to be elicted by pressure in the right iliac fossa; the invasion of the disease may also be preceded by a short prodrome, and be ushered in by an abrupt, distinct chill and fever, which have the exact form of quotidian intermittent or remittent fever. The affection may arise in summer, and make its home on very breezy heights.

In attacking a fever whose true form is not yet manifest, we do well to be wary. Should we deem it malarial, and proceed to purge the patient, we shall have hypercatharsis of the alvine canal—have the sensibility to irritants usually found in a typhoid subject. If we administer cautiously and rationally to the presenting symptoms, our way will become clearer before us. If we have declined at the outset to announce a special diagnosis, symptoms may arise to dissipate our doubts. If we see the patient at a suitable hour, morning and evening, we may find the fever assuming the specific rise and fall, the condition of tongue and pulse may correspond; there may be epistaxis or tympanites, or deafness, or delirium, or any of the many symptoms so accurately recorded by authors; but scarcely ever shall we have all the points—even the most characteristic may be absent. Should there be a series of cases, we may have the absent symptoms supplied by them.

The writer, after seeing much of the disease during his pupilage, treated some easily recognized cases in 1851. When he encountered it afresh in 1862, it was under a very different aspect. The first case presented no symptoms that could be deemed diagnostic of typhoid fever. It was indeed continued; there was a very slight, hacking cough, with a *rale* scarcely perceptible, and an irritability of temper and impatience not greater than in any nervous sufferer in an ordinary fit of sickness. A series of eight cases in this patient's home, extending over a period of several months, served to clear up the diagnosis. The specific symptoms appeared, one by one, in the various cases: hardness of hearing, epistaxis, tympanites, diarrhœa, mental hebetude, morbid vigilance, rose-colored spots, black fissured tongue, etc. However much the cases differed among themselves, there was no difficulty in assigning all to one cause.

It was well, perhaps, that I was not at first able to distinguish this as typhoid fever, because I was led to treat it symptomatically, and my mind was not fettered by believing that it was a self-limited disease, and little liable to be affected in its duration, or even in its severity, by treatment. In combating it with large doses of quiniæ sulphate without regard to the periods of exacerbation—a course then, and long after, held by prominent teachers to be inadmissible—I found that the fever steadily and surely declined in its severity, and that nearly all the patients recovered. When the disease had so far unfolded itself upon successive sufferers in the same family that its type and character could be pronounced with certainty, there seemed to be no necessity for change in the method of treatment. The antipyretic effect of quinia in continued fever was as firmly established in my mind at that time, as had heretofore been its antiperiodic quality. The disease was unquestionably shortened by its use, and dangerous symptoms failed of development in most of the cases by its capacity to diminish heat, and to counteract the other baneful effects of the noxious principle giving rise to the outbreak.

A correspondent of the Reporter in western Virginia uses the term "hybrid" to designate a fever occurring in his locality having the general characteristics of typhoid fever, but accompanied by one or two symptoms usually associated with fevers assigned to a terrestrial origin. It is to be regretted that the author used this term, which he immediately proceeds to correct in the sentences following, as it is echoed by another correspondent in a distant State. I think few medical men of extended observation will admit the idea of hybridization in disease. The affluents of certain rivers bring to the

main trunk waters highly colored from the soil they have traversed, and by the violence of their current may, for a time, give a distinct impulse to the main body of the stream, but they are soon merged and lost in the general volume, and indistinguishable in the general flow.

In the MEDICAL AND SURGICAL REPORTER, vol. xlvii., p. 421, I detailed with extreme minuteness what may be fairly termed a model case of typhoid fever, though it bade fair at first to be a so-called "malarial" fever. The prodrome occupied but three days, and was succeeded on the fourth and fifth days by chills and fever of a pronounced intermittent type. After that, the special features developed in due order, one condition being present which is quite rare, viz., a strong tendency to convulsion.

In traversing the signs exhibited by the epidemic at Martinsburg, it will be noted that they have a closer reference to typhoid than to malarial fever. The tardy development, epistaxis, iliac tenderness, alvine hemorrhage, the evening exacerbation and morning remission, all point in that direction, while the lack of appetite, loss of strength, and the condition of pulse and tongue, are quite constant in this affection.

The grave symptoms referable to the brain and the intestinal glands in bad cases, doubtless failed of development by the repressive effects on the pyrexia of the remedies employed.

On the whole, I should be inclined to invert the order of the diagnosis made, making it read, "Typhoid fever, modified by malaria of paludal origin, but in no sense 'a hybrid.'"

"RUPTURE OF THE SPLEEN."

BY GEORGE G. GRAHAM, M. D.,

Assistant Physician Western Pennsylvania Hospital for the Insane, Dixmont, Pa.

A. S. H., male, aged 35, married, laborer. Admitted to this Hospital November 27, 1885. Was suffering from chronic mania of eighteen years standing. Was in very poor health, and said to have had epilepsy for twenty years. During the past year he has had an average of one epileptic seizure every two days. Tonics and bromide of arsenic were prescribed, under which treatment he improved very much, only having had one convulsion during his residence in the hospital. This convulsion occurred December 14, 1885.

December 15, 1885. Patient very much excited since convulsion of preceding day. At 3 o'clock p. m., an accident occurred in the ward in which blood was drawn, at the sight of which the patient fainted, falling from the bench on which he was sitting to the floor. He was immediately placed in bed, and in a short time recovered consciousness. After this he was much quieter and less excitable. He ate his supper, and at 8:30 o'clock retired to bed, to all appearances in as good condition as usual. He slept well until 2:30 o'clock a. m., December 16, 1885, when the attention of the night-nurse was attracted to him by his groaning. Upon seeing the patient's condition, the nurse notified me, but as I was ill, my friend and colleague Dr. McKennan kindly answered the summons. When he arrived, he found the patient's condition as follows: Intense collapse, extremities cold, no pulse at the wrist, no heart-sounds could be heard, respiration labored, rapid, and shallow. Complained of intense pain in the region of the heart, and cried out every few minutes. Was delirious, very restless, and crying out that he was going to die. A diagnosis of "heart clot" was made, and free stimulation commenced immediately. Hypodermic injections of aromatic spirits of ammonia and whisky were given every ten minutes. External heat also applied. In about 30 minutes a feeble pulse-beat at the wrist could be felt, but the heart-sounds, although distinguishable, were very much confused and rapid. Left him in about one hour, with directions to the nurse to give the stimulauts by the mouth every thirty minutes during the remainder of the night. In the morning he was somewhat better, reaction having been established. Carbonate of ammonia was substituted for the aromatic spirits, and he continued to improve during the day; but in the evening pulmonary engorgement set in, and he lingered on until the 19th of December, when death occurred.

Post-mortem thirteen hours after death. No bruises or signs of external injury were observable on the body. *Chest* opened first. *Lungs* found to be very much congested and completely filled with fluid. *Pleural cavities* were filled with a straw-colored serum. *Heart* normal in size, venæ cavæ filled with blood. *Left heart* filled with post-mortem clots. *Right heart* found to have a large ante-mortem clot formed among the columnæ carneæ and extending intot he pulmonary artery. The entire clot measured fifteen inches in length. *Abdominal cavity* next opened and found to contain a large quantity of blood, and on examining to find the

origin of this blood, the *capsule of the spleen* was found to be ruptured on its anterior margin and surrounded by a large clot. The clot being removed, the rupture was found to be one-half inch in length. The body of the spleen was, to all appearances, normal, neither being enlarged nor softened. This rupture not being extensive, hence permitting the blood to escape but slowly into the peritoneal cavity, is probably the cause of the collapse not coming on for some hours after the fall. The patient's reacting from the collapse and improving for twenty-four hours thereafter was no doubt due to the prompt stimulation afforded by the doctor (for the patient would certainly have died at that time without it) and to the clot which had formed around the spleen preventing further hemorrhage into the abdominal cavity. To my mind the rupture occurred at the time of his fainting (December 15), and although no bruise could be found, or other symptom isolated that would point to such a serious injury to that organ, yet I do not doubt that it was caused by his fall from the seat.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. James H. Hutchinson

Bright's Disease.

You will remember, gentlemen, the colored woman who was before you at the last clinic, suffering from an acute exacerbation of a chronic kidney trouble. You remember how very marked was the general œdema, what great dyspnœa the woman suffered from, and how critical was her condition. She had, you may remember, symptoms that warranted me in saying that she had, conjoined with her kidney trouble, disease of the heart and liver. Well, after her appearance at the clinic, she grew rapidly worse, not, however, in consequence of being brought down here, but because her system was unable to further oppose the progress of the combined diseased condition. You remember that she had not only œdema of the walls of the abdomen, but also ascites, for I could readily detect fluctuation. This accumulation was not so very great, but it was enough to embarrass respiration. The day after she was before you, I tapped the abdomen, but got no liquid. I would not have considered this a justifiable operation under ordinary circumstances, but the impediment that the collection of fluid offered to respiration imperatively called for the operation. As I say, I got no fluid, but after death the abdominal cavity was found to contain an abundance of liquid. Why I did not get it I am not prepared to say, for it was found that the puncture made by the trocar was below the level of the liquid. It is true that some fluid leaked from the orifice after the operation, but I did not get a free flow, as I had a right to expect from the amount of liquid that was in the abdomen. Well, as you may infer from what I have said, the woman died. I have here the specimens before you. You will see that the aortic valves are diseased, there is stenosis of the aortic orifice, which was the cause of the direct murmur with the first sound of the heart, that was heard during life. So, also, you see a thickened condition of the mitral valve which accounts for the indirect murmur to which I called your attention. The intensity of a mitral murmur is heard over the apex of the heart. If there be two murmurs, as there were in this case, we will, upon auscultation, hear the mitral murmur most distinctly, as I have said, over the apex of the heart, then, as we move away from this point, it will become less and less distinct, and as we approach the aorta we will commence to hear the other murmur, from which fact we infer that it is aortic in origin. It will also sometimes happen, but not always, that these two murmurs vary in character. They do not always do so, hence we must place most reliance upon the locality in which they are heard most distinctly.

Now, in such a case as this it is obviously impossible to say which organ was the point of departure of disease—whether the heart disease caused the kidney disease, or whether the condition of the kidneys caused the disease of the heart. Here we find a contracted kidney with an adherent capsule and a urinous odor to the organ. This odor has, by some authorities, been supposed to belong especially to the contracted kidney. The liver is somewhat contracted, which is what we would expect to see, for I told you that the woman had led a reckless, dissolute life. The fact that we have valvular disease rather inclines me to the belief that the cardiac mischief antedated the kidney disease, for when the heart is deranged as a sequence of nephritis we usually have merely hypertrophy and no valvular trouble. I am inclined to the view, in this case, that the kidney disease is merely one expression of the general thickened, stiffened, fibroid condition of the vessels throughout the whole system.

This condition of the vessels, as Dr. Johnson has pointed out, interferes with the freedom of the circulation; they exert a stop-cock action, as it were, because their contractility no longer favors the passage of the blood; hence the heart, compelled to make unusual efforts to overcome this obstruction, becomes hypertrophied.

Now, here is another colored woman, whom I also showed you last week, and who was almost a counterpart of the one from whom these specimens were obtained. At that time she really seemed to be the iller of the two, yet while the former case has died, this woman has made a comparative recovery. She has been in the hospital, as I told you, several times before. She is one of those cases of chronic cardiac and kidney disease that you frequently meet, where the patients will get along quite comfortably so long as they are not subjected to any strain. The great point in the management of such cases is to so ordain their lives that what is chronic shall not become acute, for in these cases the great danger to be apprehended is the supervention of an acute attack, which the depraved system is not able to oppose. In this case the woman's father died of dropsy, which is, of course, a very vague expression, but which may have been due to kidney disease. She has a somewhat uncertain history of syphilis, and she tells us that she had a severe attack of rheumatism when she was eighteen years old; but that she was subject to œdema even before that time. She has, during her history, been obliged to rise frequently at night to urinate, sometimes as often as twelve times; and this is an important symptom, for in many cases this very frequant micturition is one of the earliest symptoms of Bright's disease, manifesting itself some time before any other symptoms become evident. Therefore, whenever a patient tells you that she has to rise frequently at night to urinate, your thoughts should at once revert to the kidneys. She also suffered very much from dyspnœa and persistent headache. She makes the very vague observation that her whole family have been subject to tumors and dropsy, which is the character of statement that you would expect to receive from a colored woman. She has been in the hospital three times before her present admission, suffering with general œdema. She has a double murmur, one heard over the aorta with the second sound of the heart, which I take to indicate aortic regurgitation, and one with its point of greatest intensity over the apex, also with the second sound, which tells us that she has mitral regurgitation. In the urine I find granular, epithelial, and hyaline casts, the specific gravity is 1025, and it contains albumen. The trouble with respiration was very great. The treatment consisted in counter-irritation to the chest, with the view of relieving the engorgement and congestion of the lungs that was a very threatening feature, and she was given digitalis and Basham's mixture. At first the dyspnœa was so great that she could not lie down, but now you see this condition has been much relieved. Sometimes, in these cases, the dropsy of the legs will become so great as to seriously interfere with their circulation, and we may, as a consequence, have sloughing of the integuments. When such threatens, we should relieve the strangury by incisions. When I percuss this woman's chest I find an increased area of cardiac dullness, but the mammary gland is so large that it interferes very much with the completeness and accuracy of this examination, and such is a complication that you will not infrequently encounter. However, though I cannot accurately map out the area of cardiac dullness, yet the position of the apex beat, taken in conjunction with other signs, makes me satisfied that the heart is enlarged. The aortic cartilage is the second cartilage on the right side, and when I place the stethoscope over this point I hear a murmur that is double, so that in addition to the regurgitation, which I have already mentioned, there must be some roughening of the aortic valves, which causes a murmur to be produced when the blood flows over them on its exit from the heart. The pulmonary cartilage is the second cartilage on the left side, and here I detect a marked accentuation of the second sound, which tells us that there is mitral regurgitation. Such signs, that is a murmur with the second sound heard about the pulmonary cartilage, with accentuation of the second sound, are almost pathognomonic of mitral regurgitation, and when we hear this murmur posteriorly, at the angle of the scapula, we can be quite sure of its origin. So, also, as I tell you, she has kidney disease. You see here the line of albumen at the junction of the urine and the nitric acid in the test tube; if this precipitate were from the urates it would be from above, and would not be so distinctly outlined. As I say, in such cases, the treatment must consist in vigorous counter-irritation to the chest, and in stimulating the renal secretion. If we have time, if the case be not too urgent, we should resort to diuretics to remove the dropsy, but if the condition is more threatening we will be compelled to use hydragogue cathartics, and

I know of none more serviceable than elaterium, or we may relieve the œdema by means of copious sweating with pilocarpine. The woman has very much improved, and her treatment now will consist of rest in bed, with the infusion of digitalis and Basham's mixture.

Cerebral Embolus.

C. H., a Swede, was admitted to the hospital January 15. She had measles when a child, has no syphilitic history, is married, has had two children and one abortion. Her labors were very severe. Her menstruation is and always has been normal. She has never had rheumatism, but has complained, at times, of palpitation and dyspnœa, though she is not subject to fainting or attacks of epilepsy. As a rule, her bowels are costive, alternating with an occasional spell of diarrhœa. Her appetite is good. To come down to the history of her present attack; while in her usual condition of good health, after a day's work, she suddenly lost power in her left side and fell to the ground, though she did not lose consciousness. She was able to get up and walk a little distance, when she fell again. She finally reached her home, and for some time was paralyzed in the left side, which condition has been gradually less marked. She also suffered from nausea and headache, and formication of the left arm. She has, as you see, a large frame, and is well nourished; the eyes are sensitive to light, and she has suffered from intense frontal headache. Sensation is slightly impaired on the left side, and the reflexes are somewhat exaggerated. An examination of the urine failed to reveal anything abnormal. She was given small doses of calomel and soda, and counter-irritation was made to the back of the neck. Ophthalmoscopic examination revealed blood in the margin of the disc of the left eye. She is getting better now, and she has been put upon the use of iodide of potassium, and the small doses of calomel continued. When the gums are touched the calomel will be suspended. Well now, at first this looked like a case of apoplexy; but when we have a hemorrhage into the brain there is usually loss of consciousness, which was not the case here. She felt a sensation of faintness before falling. Apoplexy is usually more sudden in its onset, the patient receiving no warning whatsoever. In apoplexy we usually have the history of some previous diseased condition; not so here. We do have here some very slight heart murmurs. Well, now the question of cerebral embolus offers itself to us, and this I think to be the true explanation of the case. Some small clot has been detached from the aortic valve, and washed into a vessel of the brain. Against this theory is the fact that the left side is not usually affected in embolus. There has also been some fever here, which is not a necessary accompaniment of embolus. The onset of the attack is, however, like that caused by embolus. It may be that the plug does not completely occlude the artery into which it is washed, and in such a case we would have the comparatively gradual onset of the symptoms, as we did have here. As a clot formed around the embolus, the symptoms would become more pronounced. The choked disc and fever may mean meningeal inflammation, following the embolus. The neck was retracted, and when the head was lifted the shoulders came with it, as we would have in meningitis. The artery that has been occluded will never be restored to its former condition, but collateral circulation will be established, and the woman will be restored to comparative health. Such a case would have formerly been called apoplexy.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. Theophilus Parvin.

Uterine Applicators.

Dr. Parvin gives the class a practical point about the selection of uterine applicators. As a rule, they are made of copper with a wooden handle; at least, very many are so made; and their construction, when so made, is faulty. The handle is very apt to get loose. You should select an applicator made of malleable silver, and one where the handle is continuous with the instrument. Such an instrument will cost a little more than those made of copper and wood, but they will be much more satisfactory, hence cheaper in the long run.

Vascular Tumor of the Meatus.

Here is a woman who had a syphilitic husband. Some years ago she had a growth removed from the vulva, which has left much deformity thereabouts. It looks as though she had lupus, but, of course, this tumor may have been entirely independent of the syphilis. She comes to us now with some kind of a growth about the meatus, which gives her great distress. Now it is a question in my mind whether this growth is syphilitic or malignant; I am inclined to think that it is not specific, for my impression is that it is a simple vascular growth. Now I remove it with scissors, and you see

I receive a jet of urine from her bladder on my clothing, which reminds me that I forgot to empty her bladder before operating, a precaution that should always be observed.

SERVICE OF DR. ROBERTS BARTHOLOW.

Epilepsy.

Here is a child who is subject to epileptic seizures and who presents to us for treatment a paralytic condition of the lower limbs. He had his first convulsion when he was nine days old, and has had them off and on ever since. Now, the fact is presented to us in this case, that is peculiar and to which Dr. Jackson first called attention, that when a convulsion comes on these paralyzed muscles are implicated. It seems singular that muscles that are so paralyzed as to be absolutely without the control of the will, should be made to act violently under the stimulus of a convulsion, but such is a fact that has been abundantly observed. In this case the convulsive movements begin in the paralyzed limbs. We have in this case the usual deformity produced by paralysis and consequent deprivation of exercise. We also notice from the expression of the boy's face that his grade of intellect is not very high, and as he grows older this defect will become marked. Now, the important point in such a case is to inquire what we can do to relieve the little sufferer. So far as a cure is concerned, we cannot hope for much; the chances are that we have to do with an intracranial lesion. But we can help such a case by devising an apparatus that will enable him to get about and thus derive the benefits of exercise. We will also use faradaism if the muscles will respond to it; if not, they may respond to galvanism; if so, we will use galvanism until the reaction to faradaism is restablished. It is really marvellous how much we can sometimes do in these apparently hopeless cases by the continuous use of electricity, aided by massage. We will also improve the boy's general condition and give him the bromides.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated meeting, January 14, 1886.

The President, J. C. Wilson, M. D., in the chair.

W. E. Hughes, M. D., Recorder.

Dr. T. S. K. Morton presented a "Cancer of the Lower Third of the Œsophagus, with Metastases to the Stomach and Liver," from a woman æt. 61 years, of good family history. Her illness commenced, by her account, eleven weeks before her death, with jaundice, vomiting, constipation, and lancinating pain in the right hypochondrium. The vomiting became uncontrollable, the matters several times containing coffee-ground material. After death there was found a scirrhus cancer of the lower third of the œsophagus, extending to the stomach, with no narrowing of the œsophageal lumen. The retro-peritoneal glands were involved, and the head of the pancreas slightly. Scattered through the liver and stomach were numerous secondary nodules.

Also "Cirrhosis of the Liver with Perihepatitis," removed from the body of a woman æt. 40 years, who had been an excessive consumer of strong spirits. Symptoms had been present for five years, the most prominent of which were the general œdema with marked ascites and diminution of the area of liver dullness. She died of an intercurrent attack of facial erysipelas. The liver weighed 36 ounces, and was strongly adherent to neighboring structures. At its entrance into the liver, the portal vein was much contracted, and below this point dilated.

Also "Amyloid Degeneration following Chronic Dysentery." The patient, a girl æt. 20 years, had no history of syphilis; there was a perfectly good family history. She had been in poor health, but with no positive symptoms, for two years. Last summer she had whooping-cough. After that she improved steadily till three weeks before her death, when profuse diarrhœa with high fever set in. This was the first attack of looseness of the bowels she had had. Jaundice gradually developed. The liver was found to be enlarged. The urine contained albumen and casts. The diarrhœa persisted, the passages containing blood and pus. At the autopsy, the liver, spleen and kidneys were found infiltrated with amyloid material, and the large intestine throughout was in a state of chronic dysenteric ulceration. Dr. James Tyson said this was the first case he had ever met with in which there was this association of amyloid disease with dysentery as the ctiological factor, although this seems the only possible cause in this instance, where the possibility of syphilitic disease seems excluded. Dr. W. Osler thought it was well recognized that chronic dysentery might be followed by extensive amyloid disease. He had met with one or two instances in connection with chronic diarrhœa, which post-mortem

examination showed dependent on chronic dysentery, with very much the condition of bowel present in Dr. Morton's specimen.

Dr. Osler presented a "Spindle-celled Sarcoma of the Retro-peritoneum, with Extensive Thrombotic Degeneration," and gave a history of the case. A man, æt. 60 years, was admitted to the University Hospital in September, 1884, with an abdominal tumor which had been noticed for about six months. He had lost flesh and strength, but there was no pain. The tumor formed a solid mass occupying a median position, extending above the umbilicus, could be readily separated by palpation from spleen and liver. The case was regarded as one of Lobstein's retro-peritoneal sarcoma. For several weeks the patient passed daily over seven pints of clear urine of low specific gravity without sugar or albumen. The patient was subsequently admitted to St. Mary's Hospital under Dr. O'Hara, and while there Dr. Mears aspirated the tumor, the upper part of which had become soft, and drew off nearly two quarts of bloody serum. At the autopsy the tumor was found to occupy a central position, was covered by peritoneum, and was attached to the tissues in front of the symphisis pubis, and seemed to have grown from the subperitoneal connective tissue in this region. The upper part of the mass was represented by a soft fluctuating cyst containing blood and shreds of firm thrombi; the greater part formed a solid mass, which on section presented a brownish-red color, was firm, dry, and had all the appearance of an old unstratified thrombus. In an area at least 8 x 7 inches this remarkable condition existed. At the lower part there were two or three greyish-white masses, evidently of a sarcomatous nature. The capsule was formed of condensed fibrous tissue, beneath which in many places were recent extravasations. The weight was estimated as at least eight pounds. The lymphatic glands were not enlarged. The kidneys were fibroid. The liver presented several secondary masses, one the size of an orange. Microscopic examination showed the primary and secondary masses to consist of closely-packed spindle-cells. The reporter drew attention to the rarity with which spindle-celled sarcoma forms a large abdominal tumor, and to the unusual site of origin. The most interesting feature was the remarkable transformation which the greater part of the mass had undergone. This was attributed to repeated hemorrhages and the gradual conversion of the extravasated blood into a dry, hard thrombus. Such a thrombotic change in a tumor was most unusual, and he had not been able to find reference to a similar instance. A third point referred to was the polyuria, which was doubtless due to irritation by pressure on the renal nerves, and lastly a reference was made to the facility with which the growth might have been removed.

Dr. J. E. Mears thought the growth could have been removed, though the removal would have been attended with some hemorrhage.

Dr. Tyson would like to ask Dr. Osler what, in his opinion, was the effect of thrombotic degeneration on the histological elements of tumors; and, again, is it possible for clots to be converted into the tissue of the original tumor, as is asserted by some?

The President remarked that the case was of much interest from a clinical standpoint, in view of the possibility of surgical interference, and asked Dr. Osler whether the conditions as found post-mortem suggested any means by which such a tumor as this could be diagnosticated from a similar growth occupying the more usual position in the lumbar region.

Dr. Tyson, in connection with the clinical history, called attention to a retro-peritoneal sarcoma presented by him to the Society last winter, which had been mistaken by him and others for a tumor of the kidney.

Dr. Osler, in reply to Dr. Tyson's first question, stated that the only remnants of sarcomatous tissue were two or three small, but very distinct, portions in the lower attached part of the tumor; the remainder had wholly undergone this thrombotic change, and in the upper part had been converted into a blood-cyst. This change was no doubt slow, with first a destruction of the sarcomatous elements by the blood clot, and then a slow process of necrosis. There was no evidence in any part of the tumor of an invasion of the coagulum by the sarcomatous elements, as is not infrequent in thrombi in other regions, as he had seen in the portal and renal veins. The chief interest in the specimen lies in the remarkable extent of the thrombotic change. Looking at the clinical aspect, he had diagnosticated the case as one of retro-peritoneal sarcoma, from its large size, its being so centrally placed, its slight movability, its distinct separation from liver, kidney, and spleen, not being placed more on one side than on the other, and from the fact that palpation in the lumbar regions gave no pain or other evidence of kidney lesion. It was firmer above the brim of the pelvis than any other tumor he had ever ex-

amined. One remarkable feature about these tumors is their painless character; this man complained of no pain, and in two other similar growths, which he described at length, pain was not a symptom.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, December 3, 1885.

The President, B. F. Baer, M. D., in the chair.

Some Causes of Tardy First Stage of Labor, and their Treatment.

By Elliott Richardson, M. D.

The following cases have been of interest to me, and I trust will be so to others. Most of them represent instances of certain forms of dystocia, which are neither new nor very rare, and the treatment of which is often a matter of censure to the accoucheur.

Mrs. M., æt. 28 years, born in England, a very light blonde, of more than medium height, and apparently well-formed, was taken in labor with her first child early in the morning of February 18, 1883. Her previous history was uneventful in a clinical point of view, no evidence having been elicited of any protracted or violent illness, or of hereditary taint of any kind. The pains were not at first severe, but became more so as the labor advanced. I saw her in the evening of the 18th, when I found the os dilated to about the size of a quarter of a dollar, thin, but soft and not sensitive to the touch. During the pains, the bag of waters, which was very small, seemed to press but lightly through the os. Through the membranes the presenting head was felt in an attitude of semi-extension with the anterior fontanelle occupying nearly the centre of the field. The occiput was directed toward the left acetabulum. The presenting head was held at the superior strait, and did not advance during a pain, but it so closely fitted the lower segment of the uterus as to completely separate the amniotic cavity above from that below, and to prevent any addition being made to the small amount of liquor amnii contained in the bag of waters. Nor did the head show any disposition to become flexed either during a pain or its absence. Labor continued with moderate pains during the 19th and 20th, with but little effect upon the os so far as could be perceived by the touch, although it was evident that a very slow dilatation was being effected. The condition of the patient during this time remained good, and gave no occasion for anxiety or alarm. On the morning of the twenty-first day, the fourth day of labor, however, symptoms of exhaustion became apparent. The pulse ran up to over 100 per minute, and increased bodily heat was associated with a tendency to dryness of the mucous surfaces. Still but little progress had been made in accomplishing the dilatation of the os, which was at this time opened to about the size of a half-dollar. It was still impossible without artificial dilatation to attempt either version or forceps delivery. The head had not advanced, and still plugged up the lower segment of the uterus as effectually as ever.

Two courses were open to me—one was to dilate the os artificially and apply forceps or turn, the other was to support the patient's strength by securing to her needed rest, while at the same time promoting perfect relaxation of the soft parts, hoping that sufficient dilatation would, under this treatment, soon enable me to rupture the membranes, when the head being exposed to pressure from the uterine contractions above it would fairly engage, and, it was hoped, descend through the os uteri and the superior strait. The latter course was chosen, and in order to carry out the treatment a sixth of a grain of sulphate of morphine was given every four hours, while the severity of the pains was still further mitigated by inhalations of chloroform at the beginning of each pain. Under this treatment the general condition of the patient improved; she slept regularly between the pains, and in that way got much rest. By ten o'clock in the evening sufficient dilatation had been secured to justify me in rupturing the membranes, when the head descended and soon the second stage of labor was established. This terminated successfully for both mother and child at about eleven o'clock that evening. Thus was the labor happily and safely concluded, after a duration of about ninety hours, by the use of constitutional means alone. The external measurements of the pelvis subsequently taken with care, showed the following dimensions:

Between ant.-sup. sp. proc's	$8\frac{5}{8}$ inches.
Between crests	$10\frac{1}{2}$ inches.
External conjugate	$6\frac{1}{2}$ inches.
Real conjugate by inference	$3\frac{1}{2}$ inches.

The relation of the measurements of the distances between crests and ant.-sup. spi. processes precludes, almost to a certainty the existence of a rachitic pelvis, and os. All the measurements were somewhat below the normal; the small pelvis was probably one of

those in which the sexual development of the pelvis was imperfect, that is, arrested in its progress. The attitude of partial extension observed in the fœtal head in the case just given is explained by the fact that the extremities of the narrowed conjugate diameter formed the points of resistance to the descent of the head, and as they would naturally offer much more obstruction to the descent of the greater diameters near the occipital extremity than to the narrower ones near the face, the latter extremity would of necessity descend first. In the last day of the labor I had the benefit of the advice of Dr. Albert H. Smith, who then, for the first time, saw the case with me.

On March 25, 1885, I saw, in consultation with Dr. Hampton, Mrs. M., in labor with her first child. She had been in labor for nearly twenty-four hours without making any great apparent progress. On examining I found the os dilated to about the size of a half dollar, and presenting no abnormal conditions. The bag of waters was small, and did not seem to press with any force through the os during the pains. The head presented in the second position, and was held in a partially fixed attitude at the superior strait. The patient was much alarmed by the slow progress she was making, so that the pains were becoming very rapid without materially aiding in the advancement of the labor. The treatment adopted in this case was rest in bed, one-sixth grain of morphia every twenty-four hours, and inhalation of ether at the beginning of each pain. The membranes were ruptured as soon as a greater amount of dilatation had been secured, and twelve hours after I saw the case she was safely delivered of a living child. No opportunity was afforded me to measure the pelvis after the termination of the labor. This case differs from the first in degree only, the nature of the impediments to the progress of the labor being the same. In both the dilating wedge usually afforded by the bag of waters was wanting, because the closely-fitting head prevented access of any considerable amount of liquor amnii to that part of the amniotic cavity which was in advance of it, and the head itself did not advance because it was held at the brim of the pelvis by the narrow conjugate. While in normal labor, before the membranes are ruptured, all parts of the fœtus are exposed to a like pressure, because that pressure is communicated to it by the liquor amnii; when the head cannot advance, and at the same time prevents any part of the liquor amnii descending past it into the bag of waters, this equilibrium of pressure becomes destroyed, that part of the fœtus which lies above the line of contact of the head with the uterine walls receiving the full force of the contractions of the uterine muscles, while that part which is below only receives the force of resistance offered by the cervix. Hence, when the latter is soft and dilatable, a process of moulding or adaptation of the presenting part of the head occurs, during which the most depending part gradually approaches the os, and tends to dilate it by affording that dilating wedge which is absent at an earlier period of the labor. When the head by this process approaches so close to the membrane closing the os as to exert considerable pressure upon the latter, all further moulding ceases, but at the same time dilatation of the os becomes more rapid, so that soon it will have progressed to a sufficient degree to justify rupture of the membranes. The effect of such rupture is to relieve the head of all impediment to the further progress of moulding and elongation. It is now thrust downward, and, if the pelvic narrowing is not great, will soon pass through the brim and into the os. The latter being exposed for the first time to the whole dilating power of the uterus, readily yields. The peculiarity of the first stage of labor, which in all its important bearings upon the welfare of the woman and fœtus, widely distinguish it from the second stage, is that so long as the membranes are intact, the relations of the two beings to each other are precisely the same as those existing during the course of gestation, so that almost indefinite delay is perfectly consistent with the entire safety of both. Notwithstanding this fact, the first stage of labor is often a period of great danger to both. The danger to the mother is from exhaustion, and exceptionally from rupture of the uterus; that of the fœtus is from asphyxia, due to the too frequent or too powerful uterine contractions. The mother will only become exhausted when the pains become so frequent, so violent or so long-continued, that she is not able to restore her strength from time to time by sleep and perfect rest between the pains. The same condition with regard to the nature of the pains, early rupture of the membranes, and probably some abnormal state of the tissues of the uterus, are essential to the production of rupture of that organ. The risk to the fœtus is due to the same condition of the uterine contractions as those which impair the mother's strength, in which the time intervening between the pains is not sufficient for the removal of the vitiated blood from the maternal part of the

placental circulation, and the supply of arterial blood in its place. In considering the relations of the woman and fœtus to each other, and the nature of the dangers which threaten each in the first stage of labor, the indications for treatment might seem to be obvious. They are to preserve the proper strength and rhythm of the uterine contractions, in order to secure needed rest to the mother, and sufficient regularity in the placental circulation to supply the fœtus with enough oxygen for its preservation. When, therefore, it is obvious that from any cause the dilatation of the os uteri must be a prolonged process, we should take care to protect both the woman and the fœtus from danger during its progress. Even weak uterine contractions may, by becoming nearly continuous, produce the dangers already alluded to, and so while endeavoring to strengthen them, care must be used to preserve their rhythm. In the cases which I have reported, this principle was adopted in treatment. Nothing was done until the pains became abnormal in character, when the measures already detailed were instituted. In both cases morphia was used by the mouth; in one case inhalations of chloroform, in the other of ether, were used in conjunction with the opiate. In view of recent experiments, there is no doubt that ether is the safer remedy of the two, and yet it possessed so many disadvantages when compared with chloroform, and the risk of the latter when carefully used in these cases and in conjunction with the use of opium in some form is so slight, that it is a question in my mind whether we are not often justified in using chloroform in preference. During the first stage of labor, if no painful operation is to be performed, it is not necessary nor even desirable to produce complete unconsciousness. The anæsthetic is given to mitigate pain, not to entirely destroy the consciousness of it, and at the same time to prevent both mental and uterine irritability. Opium and chloroform supplement each other to a certain extent, so that when the effects of the two are combined a much smaller dose of each is required to produce a given effect than when either is used alone. This is not so with opium and ether, or to so slight an extent as to be almost inappreciable. While in a woman in labor who is under the moderate influence of opium, but a small amount of chloroform administered by inhalation is sufficient to give all the relief from pain needed, the quantity of ether to be used to produce the same beneficial effect will not be found to be less than when no opium has been given. The practical result of this relation of the remedies to each other is that in the former case the patient's suffering is relieved at once, while in the latter some time is required before any decided amelioration is experienced. In support of the above assertion, I may be permitted to quote somewhat at length from the able paper of J. C. Reeve, M. D., of Dayton, O., which appeared in the *Amer. Jour. Med. Sci.* for July, 1880. In the course of his review of Dr. Kappeler's book on anæsthetics, Dr. Reeve says: "The modification of the ordinary course of anæsthesia by the preliminary injection of morphia deserves attention . . . It is claimed for this mixed narcosis that it is especially adapted to prolonged operations, by rendering a far less quantity of chloroform necessary, the anæsthesia being continued with far less frequent repetition of inhalation; that the stage of excitement both muscular and mental is lessened, and that thereby the dangers of anæsthesia are diminished. Mollow, one of its enthusiastic advocates, goes further, and claims that the action of the morphia lessens irritability of the air-passages, and so restrains reflex action upon the heart; that in this respect its effect is similar to division of the *par vagum*; also that the morphia in small doses increases the blood-pressure by its action on the motor ganglia of the heart, and by its contraction of the peripheral vessels, thereby opposing the chief deleterious influence of chloroform from the beginning by presenting an opposition which must be overcome before the vascular pressure can sink below the normal. As to the smaller quantity of chloroform necessary for a given length of anæsthesia, the less amount of muscular excitement and the modified mental condition, Dr. Kappeler says: 'The advantages have been on various sides clinically proved, and are only seldom called in question.' The advantages claimed by this method have been denied by Demarquay, but confirmed by Heitel and in part by König. The latter does not, however, believe that the dangers from chloroform are at all diminished by the use of morphia." Dr. Reeve further stated that "none of the advantages of chloroform-morphia narcosis attach to ether-morphia narcosis," and that Dr. Kappeler's "experience . . . seems to show that in all respects the combination is injurious rather than beneficial." Reference is made in the paragraphs which I have quoted to the use of the agents mentioned in surgery alone. They apply in the main to obstetrics as well, although I do not see any

disadvantage in theory, nor have I in practice, in the ether-morphia narcosis as compared with ether narcosis alone. In comparing the effects of chloroform and ether in the first stage of labor, the former has, I believe, a decided advantage in its effects upon the os uteri in promoting relaxation. All the advantages above attached to it are at the same time coupled with its easy and pleasant administration. Against these, however, must be offset the danger from its use. Exactly how great this danger may be in careful hands cannot be told. In many cases of fatal chloroform poisoning, it has been the first few drops that have killed; in such cases, therefore, the diminished amount rendered necessary by the morphia previously given would now be a safeguard. I believe, however, that the danger is so infinitely small when thus given that we are justified in using it in painful cases of labor, especially when the chief difficulty lies in the rigid condition of the cervix or other soft parts of the parturient canal, and that in such cases the use of morphia either by the mouth or hypodermically in moderate doses greatly facilitates the accomplishment of the end in view. At the same time, I would not be understood as advising the use of chloroform instead of ether in ordinary cases of painful labor. Since in these the only object is to relieve pain, ether answers the purpose, and being the safer remedy, should be preferred.

(*To be continued.*)

Periscope.

Lead-poisoning from Drinking Water.

Dr. W. R. Thomas thus writes in the *Med. Press*, January 27:

The following have been the symptoms and signs which I have most frequently met with indicating the presence of lead in the system: A cachectic and pallid appearance, a furred tongue, unpleasant taste, dyspeptic symptoms, as flatulence, pyrosis, pain after eating, a blue or red line at the junction of the gums with the teeth, colicky pains coming on irregularly in the abdomen, pain in the back, obstinate constipation; in females, some disturbance of menstrual functions, generally amenorrhœa, sometimes for months, but occasionally menorrhagia; a deficient secretion of urine, which frequently contained albumen, acid in the urine; general pain in the extremities, and sometimes confined to the joints, considered to be of rheumatic origin by the patient; a tendency to abort, mental confusion, loss of memory, disinclination for any mental exertion whatever, general debility, paralysis of the extensors of the forearm, tremor of the extremities generally, especially of the upper, impairment of vision, attacks of gout. We know that patients suffering from lead are prone to have attacks of gout, and, on the other hand, gouty patients are peculiarly susceptible to lead.

A word about the blue line. Whenever teeth are absent, the blue line is not generally seen. Frequently when it is absent in front, I have succeeded in finding it by some of the molar teeth behind, and if absent entirely its place is, according to my experience, taken by a red line. The blue line, I believe, is formed by the chemical action of the sulphuretted hydrogen derived from the decomposing food which remains between the gum and the tooth, upon the lead of the blood or extra-vascular fluids of the gum, thus forming the sulphide of lead.

Now, why does the water we drink become impregnated with lead in Sheffield? We know that the water has to pass through a leaden pipe from the main to the house, and we take it for granted that during its passage it takes up lead from the pipe. Ordinarily water contains a quantity of air, which acts upon the lead it comes in contact with, converting it into the oxide of lead, which is partly soluble, and is carried off by the stream. Now, water not only contains oxygen, but carbonic acid also, which, coming in contact with lead, forms the oxycarbonate which is precipitated, and deposits an incrustation on the inner surface of the pipe—a protecting and almost insoluble incrustation, which effectually prevents the water from acting further upon the lead and carrying it off as the oxide, so that the old pipes are better—not so poisonous—as new ones. These are the changes that take place when water contains nothing but air and carbonic acid, but we know that it nearly always contains salts as well. Water which has been contaminated by sewage is especi-

ally dangerous, as it contains nitrites, nitrates, and chlorides, which dissolve the lead; and that which contains lime-salts, as the phosphates, carbonates, and sulphates, tends to produce a protecting deposit on the interior of the pipe; so we see that contamination by organic matter is very dangerous. Vegetable matter, such as peat, is exceedingly dangerous, and is apt to form the deleterious compounds I have mentioned.

Let us now for a moment consider what becomes of the poison which is continually being drunk by many of us in small doses day by day and year by year, and how it acts upon some of the organs and tissues of the body. It has been found deposited in the kidneys, liver, spleen, heart, lungs, brain, spinal cord, muscles, and bones. How it acts upon the different organs and tissues we do not know, although theories have been promulgated; but this we do know, that certain post-mortem appearances have been met with, time after time, showing the effect of the poison. Muscles have been found atrophied until but little else has been left but their fibrous tissues, with occasionally hyperplasia of the latter.

I believe that drinking-water containing small quantities of lead has ultimately a most disastrous effect upon the health of the public at large; giving rise to symptoms which at first are trivial and slight, but which later on become serious. I believe that it tends to produce retraction of the gums; early decay of the teeth, so prevalent in Sheffield; imperfect assimilation in stomach and bowels (owing to a diseased state of mucous membrane), with the consequent general anæmia, constipation, derangements of uterine tract, diseases of kidneys, serious affections of brain and nervous system generally, giving rise to symptoms at first slight —such as slight impairment of mental powers and general aches, and later on to symptoms pointing to more serious cerebral changes, and paralyses of different kinds.

There is a tendency in us all naturally to walk through the world, if we believe that the water generally drunk is good, never looking for disease produced by impurities in that water; but if once our attention is directed to that subject, it is astonishing how often cases turn up demonstrating that impurity.

Now we might ask what ought to be done to prevent this. As a temporary and home remedy I would suggest the desirability of using carbon filters, which deprive the water of its lead and, it is said, of its acidity—the addition of a small quantity of calcium carbonate would be useful. As a remedy at the fountain-head, the advisability of using calcium carbonate to counteract the acidity, or of charcoal, or of both, might be considered by those who, no doubt, are extremely anxious that the water should be as pure as possible. Either of these could be utilized at the reservoir. Might not the leaden pipes have an internal layer of some material not easily affected by acids or salts? is another question which has often occurred to me. These are only crude suggestions of mine, which I simply put forward for consideration.

Poisoning by Sulphuretted Hydrogen.

A communication has been made to the Académie des Sciences by MM. Brouardel and Loye on the symptoms induced by the inhalation of dilute sulphuretted hydrogen (*La France Médicale*, September 5). The experiments were made on tracheotomized dogs. When these animals were supplied with an atmosphere composed of two litres of sulphuretted hydrogen in 100 litres of air, death ensued in two or three minutes. The pupil was noticed to dilate five to eight seconds after the commencement of the inhalation, and the eyeballs became prominent. The pupil did not react to light. The vessels of the ocular fundus were much dilated. The cornea became quite insensitive; the skin could be stimulated without causing any reaction. Twenty seconds after the beginning of the experiment galvanization of the sciatic nerve by a powerful current did not give rise to muscular movements. In brief, there was disappearance of all reflex actions. After a little struggling the muscles became rigid, so that all the limbs were in a condition of forced extension, and the thorax was in a position of expiration. The contracture disappeared when the respiratory movements ceased. The urine and fæcal matters were forcibly expelled. After a few seconds the respiration became slowed, and afterwards convulsive, as the animal began to struggle. In twenty to twenty-five seconds the respiratory movements completely ceased. If the animal be anæsthetized by chloroform the convulsive respirations are not observed. The respiratory rhythm is at first slowed, then accelerated, and gradually diminished in amplitude, and respiration ceases altogether in thirty to thirty-five seconds. If both vagi be cut before the inhalation is commenced, the phenomena are said not to be altered, and the respiratory changes do not take place earlier or later. The number

of cardiac beats is diminished; there may be four instead of fifteen beats every five seconds. This infrequency does not persist, for the rate becomes normal again at the end of the first minute. The heart, though slowed, beats very strongly. The authors believe that the action of the gas on the centripetal nerves of the heart is the cause of the alteration in the cardiac rhythm. The heart does not die until respiration has ceased for two minutes. The auricles may be seen to beat for an hour after the thorax has been opened. The blood-pressure is first raised, then lowered. Excitation of the peripheral end of the vagus causes slowing of the heart all through the experiment. Galvanization of the sciatic nerve after twenty seconds have elapsed does not modify the blood-pressure. The blood coagulates rapidly, and in thin layers has a violet tint. The arterial blood analyzed after the arrest of the heart's action is said to contain enough oxygen to support life. When a mixture of half a litre of sulphuretted hydrogen in 100 litres of air was inhaled, death followed in from seventeen to fifty minutes. The ocular phenomena were the same as with the larger dose. The cornea, at first insensitive, becomes sensitive as the respiratory movements reappear. Contracture of the limbs is noticed fifteen seconds after the commencement of the experiment, but it disappears on the return of respiration, though it may recur several times. The respiratory movements are at first ample, then slowly cease, and disappear at the end of thirty seconds. One minute later powerful respiratory movements are observed. The inspirations gradually increase in amplitude, whilst the respiratory rhythm gradually diminishes till death. The respiratory capacity of the arterial blood is diminished. The urine often distends the bladder, and may contain both albumen and sugar. The muscles are said to respond to electricity after death, and excitation of the motor nerves is also efficacious. The authors regard the death from the stronger dose as due to the influence of the gas on the nervous centres alone, whilst in the weaker doses the nervous phenomena are complicated by those of asphyxia. These observers promise to treat of the medico-legal aspects of the subject in a future paper.

Deafness in Bright's Disease.

Dr. J. Walker Downie thus writes in the *Glasgow Med. Jour.*, December 1885:

Amongst cases of interest, alike to the aural specialist and the general physician, which I have been called upon to treat within the last twelve months, was one of deafness in a patient suffering from Bright's disease.

I am the more constrained to bring this case before the readers of the *Journal*, as in referring to works specially bearing on diseases of the kidneys, auditory disturbances I find to be all but unnoticed.

On December 4, 1884, I was requested by a medical friend to see a patient of his. The patient, a warehouseman, aged 27, and married, was suffering from chronic nephritis, and on account of the swelling of his lower extremities had been confined to bed almost constantly during the two previous months. Two days before date he had been seized with sudden deafness, of which the following are the particulars, with subsequent progress:

Before December 2 his hearing was good. During the night of the 2d he was prevented from sleeping by a constant and severe pain in the right ear, which, however, did not affect his hearing. To get relief from the pain, patient had a few drops of warmed whisky and laudanum placed in the meatus several times during the night, with but slight benefit. In the morning the pain had gone, but he found himself to be completely deaf in the right ear.

It was then I saw him for the first time. On testing his hearing power with watch, the tick of which in normal hearing is audible at fifty inches, I found hearing on left side normal, while on the affected side the tick was not heard even on firm contact. Examination, with aid of speculum, showed nothing abnormal, and with careful use of Eustachian catheter the tympanum was readily inflated, but without improvement in hearing power.

The condition of his ear remained unaltered till the 16th of same month, when there was a slight return of pain in the right ear, and his left became similarly painful—"an aching pain deep in the ear"—and on the following morning he found he was equally deaf in both.

With watch, even in contact, he could hear with neither ear. Vibrating tuning fork applied to cranial bones, as also to the teeth, was not heard; but on shouting loudly to him he could make out some words indistinctly. Questions had to be put in writing.

On both sides the meatus and membrana tympani were normal in appearance, and both Eustachian tubes were permeable. He continued, to all intents and purposes, absolutely deaf till 29th of same month, when he was able to hear a little with the left, and

on 31st with the right, and in two days more his hearing was completely restored.

Desquamative Prostatitis with Hyaline Casts.

Before the Clinical Society of London (January 8), Sir Andrew Clark related a case of acute prostatitis, with discharge of hyaline cylinders resembling renal cylinders, seen by Sir James Paget and himself. The chief interest lay in the circumstance that during the whole course of the case there were found in the urine hyaline cylinders and small flask-shaped hyaline masses, which in some instances were connected with the cylinders. The patient recovered by resolution. It is nearly seven years since the date of the attack, and the patient, a medical man, has remained quite well. Sir Andrew Clark alluded to two other cases, also of medical men, which had come under his personal observation. They might be mere curiosities of medical experience, but as no reference to the discharge of hyaline casts in prostatitis could be found in standard works or special monographs, he thought the case of sufficient importance to be brought to the notice of the Society.

Mr. T. Bryant considered that the observation was one which merited careful attention. He asked in what way the casts could be distinguished from those of renal origin,

Professor Greenfield had met with four cases in which the urine contained concretions having somewhat the characters of corpora amylacea; the cases occurred in two girls and one young woman, and in one boy seven years of age. The concretions appeared intermittently. In one case he found the concretions in large numbers in the kidney after death; they stained deeply with carmine and magenta, and some with iodine. He mentioned these cases, not as of the same nature as Sir Andrew Clark's, but as worthy, like his, of further investigation.

Dr. J. G. Glover asked whether the patient had previously had a well-defined attack of gout.

Sir Andrew Clark replied in the negative to the last speaker. The characters of the casts were such as existed in the urine of cases of acute nephritis or acute congestion. A most important diagnostic point was the presence of flask-like bodies attached to the hyaline cylinders. The presence of prostatic trouble, and the fact that it was a healthy urine with the addition of a little albumen, were the conditions that favored the diagnosis of the prostatic origin of the hyaline casts. In two other medical men he had had illustrations of the same thing, but in neither of these was the disease so acute. The flask-like bodies were probably moulds of the follicles of the prostate. In the urine of women he always found a large quantity of mucus and veritable starch-granules, which were probably derived from the violet powder of the toilet.

Menstruation During Typhoid Fever.

Dr. E. Barthel, of St. Petersburg, *Deutsche Archives für klinische Medizin*, publishes a treatise on "The Retention of Menstruation and the Frequency of Pseudo-menstruation in Different Forms of Typhoid." This is a questson concerning which the authorities either omit altogether or discuss, at least some of them, in an unfavorable manner. On account of this uncertainty, the doctor endeavored to secure the necessary data from the patients in his department in Oubuchow Hospital. He did this partly through questions, partly through special examination. His material included 112 female typhoid patients.

From the information obtained, he made the following statements:

1. If the menstruation was expected during the first five days of the disease, it appeared at the proper time.

2. If the time for the menstruation fell between the end of the first and end of the second week, then it came about two times out of three. In abdominal typhoid it was absent oftener than present.

3. If the time for the menstruation to occur was after the second week, then the menstruation generally remained absent during the sickness.

4. If the time for a second or third menstruation occurred in the course of the disease, then he generally found amenorrhœa.

5. The amount of blood lost and the continuance of the same was scarcely varied by the disease.

6. Non-menstrual hemorrhage from the genitals occurred very seldom—about 3½ per cent. of the cases.

7. In some cases where the disease began during the menstruation, this ran its usual course, with the exception of one case.

8. The course of the disease never caused the commencement of the menstruation.

a. In those girls who had not yet obtained their development, who had either not menstruated at all, or only one or two times.

b. In old women who had ceased to menstruate.

c. In women who had suffered a longer or shorter time from amenorrhœa.

d. In women who had nursed shortly before or until their entrance into the hospital.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——*Shoppell's Modern Houses* is the title of a new quarterly devoted to domestic architecture, published by the Coöperative Building Plan Association, 24 Beekman street, New York city. Price, $3.00 a year, or $1.00 a number. It is profusedly illustrated, and contains numerous useful plans suited to those contemplating building.

——The Pathological Society of Philadelphia now issue a semi-monthly publication with a report of their proceedings. The editor is Dr. E. O. Shakespeare, 1336 Spruce street, Philadelphia.

——Every one interested in gardening or farming should write for a copy of the admirable seed catalogue published by Henry A. Dreer, 714 Chestnut street, Philadelphia. It will be mailed free on mentioning the name of this journal. The firm is one which we unhesitatingly recommend.

——A neat reprint by Dr. George P. Andrews, of Detroit, Michigan, on "Puerperal Pyrexia," describes in considerable detail the various morbid processes accompanied by this symptom. It is a careful study of the subject.

——The subject of the post-mortem imbibition of poisons has a great deal of importance in certain medico-legal investigations, and a recent article upon it by Dr. George F. Miller, in the *American Naturalist* for February, deserves attentive reading by those who would acquaint themselves with the facts in reference to it.

——Dr. Meigs Case, of New York city, sends a reprint of a late article on spinal disease and spinal curvature.

——In a late brochure, Dr. W. R. Chittick recommends the treatment of certain cases of serious vomiting by large doses of oxalate of cerium.

——Dr. E. C. Morgan, of Washington, D. C., forwards reprints on submucous laryngeal hemorrhage, and on the value of the snare in performing uvulotomy.

BOOK NOTICES.

Local Anæsthesia in General Medicine and Surgery. By J. Leonard Corning, M. D., etc. Cloth, 8vo., pp. 102. New York, D. Appleton & Co.

The title of this book is wider than the subject matter. The theme with which it deals is strictly the method of anæsthesia by means of cocaine, and the devices of rendering this more effective by causing a temporary venous stasis in the circulation of the part, and by raising the temperature to the degree of warmth of the blood. These ingenious plans were first suggested by the author, and they certainly add much to the effectiveness of the drug.

Guide to the Examination of the Urine. By Drs. Hoffmann and Ultzmann. Translated by F. Forcheimer, M. D. Second edition. Cloth, pp. 251. Price $1.50. Woodruff, Cox & Co., Cincinnati, 1886.

This second edition has undergone a careful revision at the hands of the translator, and a quite complete index has been added, rendering it much handier as a work of reference. The comparatively rapid sale of the first edition speaks well for the suitability of the work to the wants of the practicing physician.

The Diagnosis and Treatment of Diseases of the Ear. By Oren D. Pomeroy, M. D., etc. Illustrated. Cloth, 8vo., pp. 412. New York. D. Appleton & Co., 1886.

In this manual of convenient size the author has aimed to tell everything about the management of diseases of the ear which the general practitioner should be acquainted with. By omitting the chapters on the anatomy and physiology of the organ usually found in such monographs, he leaves himself space to go into fuller details in reference to its maladies and their treatment. He is especially full on the important subject of instruments used to improve audition, and in operations on the part. This second edition has been carefully revised, and a number of pages, as well as some illustrations, have been added, so as to render the volume an accurate representative of the science of aural surgery as it exists to-day.

——On the occasion of the tercentenary festival of the University of Heidelberg, a large gold medal was founded for contribution to the scientific knowledge of the human eye. It has been awarded to Professor Helmholtz, of Berlin, for his discovery of the ophthalmoscope.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

CONCEALING THE TASTE OF QUININE.

Probably as long as the valuable therapeutical effects of quinine are known to the profession, ways and means have been tried to correct the bitter taste of this drug, especially as its intense bitterness greatly lessens the usefulness of the remedy. It almost is impossible to administer quinine to children in any other way but in the form of pills; but no matter how well prepared, they have the serious drawback of often passing through the alimentary canal undigested; the quinine simply makes a passage through the intestines, but exerts no influence. To be sure, the drug may be employed in the form of a clysma, but first its dose has then to be augmented, and besides, its effect when thus introduced into the human organism is always precarious and not seldom nihil.

The compound elixir of taraxacum, in vogue for the last ten years, conceals the bitter taste of quinine to a great extent, provided the latter drug be mixed with the elixir immediately before its being administered, otherwise the disagreeable taste remains. Liquorice also has a good effect, and answers the same purpose as the elixir. But recently Professor Hugo Engel discovered a method which really promises to be of great value. The doctor had been in the habit of prescribing in the moist stage of bronchitis equal parts of muriate of ammonia and powdered extract of glycyrrhiza, which is besides probably the only remedy which will give relief to those patients who have a great deal of trouble, mainly in the mornings, ere they can expectorate the hardened round piece of scab and mucus, which, in consequence of a slight ulceration, is apt to accumulate in cases of chronic catarrh of the posterior nares. One to two teaspoonfuls of the compound, largely diluted with water, and taken three times daily, generally establishes a cure of this annoying complaint within three or four days, while a great improvement sets in the first twenty-four hours.

About a month ago Dr. Engel, while again prescribing this powder to fulfil a special indication in the case, added four grains of quinine to each forty grains of the powder. He told the patient, who had previously taken the powder alone, of the bitter taste he had to expect, and was not a little surprised when the patient informed him that he detected no such taste whatever. Since then, Dr. Engel has tried the same combination in a number of cases, and also induced some colleagues to make use of it, and all agree that it is the best method yet discovered to conceal the bitter taste of qui-

nine. Children usually like liquorice, and as a small dose of muriate of ammonia probably never can do harm when quinine is indicated, we possess now the means of administering quinine to young children without the trouble formerly connected with this remedy. The following combination seems to be the best for the purpose:

℞. Quiniæ sulphatis,
Ammoniæ muriatis, āā gr. j.
Pulv. extracti glycerrhizæ, gr. iv.
M.—Ft. pulvis. S.

In the same proportion, larger doses may be given, but it does not seem to be necessary to take more than ten grains each of powdered extract of licorice-root and muriate of ammonia to ten grains of quinine, so that probably after a certain quantity of quinine that of licorice need not be increased in the same ratio as has to be the case with smaller doses.

Persons with a sensitive palate, about two minutes after they have taken this compound quinine-powder, have a slightly bitter taste, which, however, soon ceases. In children it is besides the main point to conceal the taste of the drug at the time they are taking it, so that if greater experience should demonstrate the fact that a few minutes after the dose has been swallowed a bitter taste appears, we still would have gained a valuable addition to our corrigents.

We hope that some of our readers will try the combination and report the result. It is scarcely necessary to add that the muriate of ammonia and the powdered extract of licorice-root must be finely powdered and intimately mixed, and kept in a dry and warm place. There should also first be added only a little water, the same as we do in the case of flour when we wish to make a paste, otherwise the licorice swims in the form of little balls in the water, and is then difficult to dissolve. As soon as the whole—the muriate of ammonia, the powdered extract of licorice-root, the quinine, and the water—forms a homogeneous mass of syrup-like consistence, the remainder of the water, about half a tumblerful for 20 grains of the muriate of ammonia—otherwise the latter may cause griping—may be added.

ÆTIOLOGY OF INFECTIOUS VULVO-VAGINITIS OF CHILDHOOD.

Every now and then the practitioner is confronted by an angry mother, who has by the arm a frightened female child, say from two to twelve years of age, and who has at her tongue's end stories of rape and subsequent bad diseases. The practitioner immediately finds himself in a very uncomfortable position, and visions of tedious law suits and witness fees flit before him. Nothing so clears a case up as a thorough knowledge of its ætiology. Dr. J. Cséri, of Buda-Pesth, in the *Wiener Medizienische Wochenschrift*, xxxv., 1885, discusses the above subject. He says that he was induced to publish his observations through the remarkable production of Dr. E. Fränkel, which may be found in Schmidt's Jahrbucher, ccvi., p. 46.

It is generally known that one meets with a catarrhal, a croupo-diphtheritic, and a gangrenous kolpitis. The observations of Cséri have to do only with the first form—the catarrhal. In this the vagina and vaginal entrance are mostly reddened, swollen, and sensitive, and give off a secretion which is of a thick or thin fluid nature, generally free from odor. In acute cases the affection makes itself known by burning or itching. The etiological factors, which until now have been accepted, viz., external irritation, acute eruptions, scrofula, etc., are not sufficient to account for the frequent epidemic appearance of this disease. It is much more probable that a micro-organism plays an important role in this disease. Since 1883 the doctor has examined 26 cases. The children were from two to ten years of age, and were in the Children's Hospital suffering from chronic diseases. He had observed five cases in his private practice. In all cases, he found by a method which is original with himself, a 0.4–0.6 H sized coccus, which formed diplococci appearing in more or less large masses, but no chains. For the most part, as was also observed by Fränkel, he found that this coccus was attached to cells with more eccentric granulations. It resembled, in morphological relation, the gonococcus of Neisser.

In regard to the question, which is of no little importance, is the vulvo-vaginitis identical with the blennorrhœa or not, Fränkel determined in the negative. Cséri, however, thought that the arguments in favor of this decision were not sufficient, and thought, after his examination, that the identity of the kolpitis with the blennorrhœa was beyond a doubt. The clinical observations which he made were also in favor of this decision.

Seven cases were observed in the Children's Hospital at Buda-Pesth, in which more or less severe cases of conjunctival blennorrhœa resulted from a vulvo-vaginitis. Bókaisen, Hirschfeld, and Pott, also report such cases.

As the result of his examinations, the author came to the following conclusions: The vulvo-vaginal catarrh is decidedly infectious. How much it is like the exanthemata in its mode of onset must be determined by further examinations. Although it has not yet been demonstrated by pure culture that the vulvo-vaginitis is identical with the blennorrhœa, yet from clinical observation it is so proven, and also that it will infect the eye. Plain indications for prophylaxis and therapy are given by these facts.

Notes and Comments.

Compression of the Brain.

After Huegenin had finally settled the point that conimotio cerebri is not caused by a concussion of the particles of the brain tissue, but by vascular paralysis, in consequence of which arterial anæmia and venous hyperæmia accompanied by capillary hemorrhages develop, v. Bergmann, the successor of Langenbeck at the University of Berlin, has taken up the subject of compression of the brain (*Arch. f. klin. Chir.*, xxxv., p. 705).

The brain can be pressed like a sponge, *i. e.*, its fluid contents can be pressed out, but cannot be compressed. B. believes that in consequence of abnormally increased tension of the cerebro-spinal fluid, an acute general anæmia of the brain develops. He succeeded in the case of a child, 15 months old, which suffered from a meningocele, in demonstrating the tension of the cerebro-spinal fluid. By crying as well as by pressure upon the fontanelle, he was able to show manometrically the increase of pressure, and to induce such a tension of the cerebro-spinal fluid that the typical group of symptoms belonging to compression of the brain, as sopor, coma, diminution in the frequency of the pulse, and artificial pressure, set in. That the experiments tried with the same view on rabbits by various authors, had no results, B. explains by the fact that the liquor cerebro-spinalis in rabbits is too small in quantity ever to give rise to compression of the brain. Besides, Cramer has proved by his investigations that any alteration in the tension of this fluid at once causes a change in the venous circulation. In consequence therefore of an injury, the tension of this fluid is increased in the same manner as B. produced by pressure on the fontanelle; this augmented tension first causes disturbance of circulation, the latter becoming difficult, and being impeded or totally obstructed for the time being, and afterwards the nervous centres are deprived of their nutrition, and their functions cease, while the increased tension, *i. e.*, the compression, lasts.

Ovarian Epilepsy.

That many cases of epilepsy are reflex from ovarian disease we full well know, and that they can be cured by appropriate treatment is equally true. This treatment Dr. C. D. Palmer thus gives in the *Cinn. Med. and Dent. Jour.* for February. After describing a case, he says:

"We will treat this girl by keeping the bowels open daily with mild laxatives, regulating her diet, and giving abundance of nutritious food. She should by no means be allowed to remain idle. She needs both mental and physical exercise. She wants to have enough to do to keep her occupied and out of mischief, and not too much to overtax her. There should be a freedom from excitement.

"The bromides should be given three times a day in ordinary doses, at what appears now to be the ovarian molimen.

"In this case I will also apply the blister over either ovary, one at a time, anticipating the would-be attacks. I will not prescribe any iron, although she is anæmic, because the ferruginous tonics in epilepsy, probably, tend to excite reflex action. The time may come in the future when iron will do good.

"Avoid the use of emmenagogues; their effects are pernicious. It is in just such cases as this that mothers often resort to hip-baths, hellebore, savin, rue, etc. This treatment is highly injurious. It is exceedingly important that this girl be looked after regularly and faithfully, and, if possible, that these attacks be broken up now. Otherwise, as they increase in number they gain force, and become provoked from causes less and less disturbing.

"December, 1885. Patient, since receiving above treatment, has passed over three months without any return of the convulsions. The prognosis, then, in this case is very favorable to cure'; but the treatment should be continued for a year or two, although not a single fit recurs."

Chylothorax.

Dr. Kirchner reports in the *Arch. f. Klin. Chirurg.*, xxxii., p. 156, the following interesting case:

In consequence of an accident a young girl, æt. 9, was thrown against a brick wall and the right side of her chest was violently

compressed. Within three weeks chylothorax in a high degree—containing over two quarts of chyle—developed in the patient, who had previously enjoyed the best of health. Thoracentesis was performed, and though almost the same quantity of chyle again accumulated, a few weeks later a perfect cure was established, and at the time of the report, four months after the accident, the presence of any fluid in the chest could not be demonstrated. The patient had all the symptoms of a one-sided hydrothorax, and just over the third rib anteriorly there was severe localized pain and soreness. No emaciation set in, and, to be sure, the physical sign of pleurisy as concerns friction-sound was absent. To judge from other reported cases, K. believes that the thoracic duct was injured by contre-coup somewhere between the fourth and tenth dorsal vertebræ, and that the parietal pleura must necessarily also have been ruptured. The lesion probably was only a tear, or the patient possessed a double thoracic duct, an anomaly by no means rare, for otherwise the patient would have greatly emaciated. The examination of the fluid taken from the chest left no doubt of its being chyle.

In addition to his own case, K. mentions 17 others from literature, where a rupture of the thoracic duct occurred. The cause of the rupture seems always to be some accident. In one case of Bœgehold, the cervical part of the duct had been injured in consequence of an operation.

The Increase of Blind and Deaf and Dumb Persons, Idiots, and Cretins in Italy.

The following facts are gleaned from the *Ann. di Statistica*, of Rome, and the *Ann. Universal*, of Genoa.

In the Italian census of the years 1861, 1871, 1881, statistics were gathered concerning the number of persons who suffered from the above infirmities. There were found to be 100,000 inhabitants in Italy. From these we find the following:

Year.	Blind.			Deaf & Dumb.			Idiots.		
	Male.....	Female..	Average..	Male.....	Female..	Average..	Male.....	Female..	Average..
1861.	108	82	95	96	66	81	—	—	—
1871.	118	91	106	86	61	74	80	48	65
1881.	85	67	76	61	46	54	81	57	69

It is noticeable that the males suffer in larger numbers from all three of these infirmities than the females. This is also found the case in other countries.

The greatest numbers of blind were found in Calabria (the southern part), Sicily, and Sardinia, 10.6, 21.4, and 10.4 respectively, per 10,000 inhabitants. In these the greatest number of the inhabitants have dark eyes, viz., 80 per cent., 100 per cent., and 98 per cent. This testifies in favor of the assertion of Dr. G. May, that dark eyes are more inclined to blindness than light.

The most deaf and dumb were in Lombardy. In this province and Piedmont the most idiots and cretins were found. This goes to show that in Italy, as well as other countries, the mountainous sections produce more suffering from these infirmities than the level countries.

Leucorrhœal Discharges from Roller-Skating.

Dr. Von Klein writes thus to the *Boston Med. and Surg. Jour:*

"Mrs. L. consulted me about two of her little girls, Anna, aged ten, and Eva, aged twelve years. The mother called my attention to a leucorrhœal discharge which she lately observed on their clothing. An examination of the parts verified the mother's statement. I told her I could not account for it, as I had already seen it in children younger than hers, but the lady, who is of rather extraordinary intelligence, advanced a theory that their recent excessive indulgence in roller-skating brought on their affliction. Certainly, I partly coincided with her sentiments. When she returned home and spoke to other ladies about the matter, it brought out the fact that there were many others afflicted in the same way. In fact, I examined nine children in forty-eight hours, whom I found affected with leucorrhœa. These children were all roller-skaters, from nine to sixteen years of age. Their mothers steadfastly maintained that they were not afflicted before they commenced the so-called exercise. I have reason to believe that the practice of roller-skating exercise is injurious to young females, by reason of excessive movements of the lower extremities, especially of the pelvic organs, including the walls of the vagina. I trust the profession everywhere will record cases of this nature that may come under their observation, which will, I am sure, reveal many valuable pathological changes caused by the exercise of roller-skating."

Abortive Treatment of Syphilis.

More than once the opinion has been expressed that by extirpation of the indurated

primary sore we would be able to prevent the constitutional infection, while others contended that the affection of the organism has already taken place when the induration of the virulent chancre develops. To determine this question, Dr. J. Neumann has instituted a series of experiments, and published their results in the *Wiener Med. Blatter*, 1886, 2:

In ten patients he extirpated the primary induration, and in three of them the swollen inguinal glands were also removed. The effect was in all cases a negative one, for the constitutional infection was not only not prevented, but also not postponed, it appearing in each case within about two months; if anything, therefore, earlier than we observe in most cases. In the cases of extirpation of the inguinal glands, the buboes had already been in existence for four weeks, so that these cases would probably not be a correct test; but in the others no bubo had as yet set in, and the whole of the indurated primary sore, and some healthy tissue surrounding it, had been carefully removed. These researches simply prove that we do not yet possess any means by which to prevent constitutional lues, though we can surely influence its course by an early anti-luetic treatment, commenced as soon as we detect the induration, and pushed to its complete disappearance.

More about Cocaine.

Dr. George C. Catlett thus writes of it in the *Journal American Medical Association*, February 6, 1886:

1. It is an agent possessed of great potency. It acts primarily with great power and celerity upon the cerebral and spinal nervous system, and secondarily upon the heart and vascular system.

2. From its potency and rapidity of action it is liable to initiate organic lesions and functional disturbances which are uncontrollable. It is not uniform in its action, and therefore is an uncertain agent.

3. Its effects are too transient and unstable to become a reliable and efficient remedy in constitutional or organic diseases. The aphrodisiac effects attributed to it have not been observed, neither have the intense nausea and inability to vomit been observed. Its permanent beneficial effects in melancholia and allied affections are not established facts, in the writer's opinion.

4. As it is an agent of great potency, and as it is under trial to determine its limits of usefulness and danger, it should be prescribed with increasing precaution and discretion.

Poisoning from Quinine.

From the *Canadian Pharmaceutical Jour.*, for February, we learn that a case of poisoning by quinine sulphate is reported from France. A soldier requiring a purgative asked for a dose at the dispensary. The soldier in charge gave him a little mugful of what he thought was solution of sodium sulphate, and also took a like dose himself. The solution was that of quinine sulphate, and the quantity taken by each man was equal to about 180 grains of the salt. About half an hour after, symptoms of poisoning set in, the most marked features being a lowering of temperature and depression of the heart's action, with neither nervous excitement nor convulsive movements. The sensation of buzzing in the ears was, of course, strongly felt. The treatment consisted in the administration of emetics, followed, after vomiting, by strong coffee. One of the men died in a fainting fit, which occurred about two hours after the quinine was taken. His comrade survived, and in a week or two was ready for duty.

Epileptic Fits Sequelæ to Acute Rheumatism, and Cured by a Second Attack.

Dr. Hunt brought to the Sheffield Medico-Chirurgical Society the notes of this very interesting case. A young man, æt. 22, an accountant by profession, always in good health, had an attack of acute rheumatism in April, 1881. For this he was treated with the salicylate with excellent effect as regards the rheumatic fever, from which he made a good recovery. Subsequently he suffered from severe and constant pain in the head. In the following June he had the first epileptic fit. These seizures steadily increased both in frequency and severity, recurring twice and three times a week. His mental powers became affected, and he was incapacitated from attending to business. This state of affairs continued down to July, 1885, when he had another very severe attack of rheumatic fever, from which he made an excellent recovery, and with the unlooked-for and fortunate result of a complete disappearance of the fits and restoration to a perfect state of health.

Jaborandi in Bright's Disease.

We know that this drug will rapidly relieve the œdematous collection of this dis-

ease, but now, in the *Atlanta M. and S. Jour.* for February, Dr. F. H. O'Brien tells us that he feels confident that jaborandi must act in some special manner upon the kidneys, assisting nature to free the tubes when they are obstructed with epithelial or fibrous debris. He would, of course, use other remedies in conjunction with the jaborandi mixture, if indicated, such as specific tonics, purgatives, etc.

He feels that jaborandi is entitled to the credit of possessing the power of bringing about, from its continued use, favorable results, and that Bright's disease is curable, in the same sense in which we apply the word cure to any other disease in which organic changes have taken place, or, in other words, a cure would consist in assisting nature to stop a morbid process, throwing off effete material, and placing a barrier between diseased and healthy structure.

Arthritis, arising from Peripheral Nerve Lesions.

Dr. J. McArdle reports several cases in the *Dublin Journal Medical Science*, November, 1885, from which he formulates the following conclusions:

1. The lesions followed partial rather than complete nerve destruction.
2. In traumatic cases the symptoms appeared at the period of cicatrization.
3. The arthritis (unless arising from irritation of pelvic or abdominal viscera) was for a long time unilateral.
4. The symptoms resembled those of the affections styled scarlatinal, alcoholic, and rheumatic arthritis.
5. They were usually accompanied by choreæ herpes neuritis, with which they ran a parallel course.
6. When the nerve irritation is removed, a rapid disappearance of pain takes place, and gradual restoration of the joint function sets in.

A Case of Persistent Menstruation in a Lady Seventy Years of Age.

To the New York Obstetrical Society, December 15, 1885, Dr. T. Addis Emmet reported the case of a lady of seventy, whom he had known for several years. She had menstruated regularly every month since the age of sixteen, except when she was pregnant, and during a certain interval after she had reached the age of forty-five or fifty. Her daughter, who was aged fifty, also had a regular monthly flow. The mother was, as far as he knew, in perfect health, and had been a widow for thirty years. He regarded the case as a very unusual one.

Belladonna in Cholera Infantum.

Dr. Charles Chassaignac speaks most highly of this remedy in the *New Orleans M. and S. Jour.* for February, and concludes that while he does not wish to inculcate the belief that belladonna will cure every case of cholera infantum, he is convinced that future observations will prove it to be a remedy of great value in the treatment of a disease so terrible that every physician can but be delighted to possess an additional weapon with which to fight it.

Correspondence.

Two Cases of Membranous Croup Treated with Large Doses of Calomel.

Eds. Med. and Surg. Reporter:

On December 7, 1885, I was called to see a boy aged eleven years suffering with slight sore throat, for which I gave the ordinary remedies, and improvement was noticed until the 12th, when he took cold from exposure to draughts, and the disease, which was mild, developed into that most terrible of all diseases, membranous croup. Having treated a number of cases of this disease upon the plan laid down in the books with poor success, three-fourths of them dying, I concluded to try the calomel treatment in this poor unfortunate boy. On the 13th, the membrane was very firm, temperature 105°, pulse 140, respiration 40, breathing labored and heaving; cough sharp, ringing, and frequent; tongue coated, expression anxious, and every symptom that of a grave case of the disease. On the 12th and 13th he took five grains of calomel every three hours, and inhaled steam from tar, besides breathing the atmosphere that was loaded with steam from lime-water. I endeavored to have the room placed in the best hygienic condition possible, for I knew there was to be a bitter warfare for life. On the morning of the 14th the boy's every symptom was worse, and, in fact, he was almost smothered. At once I gave him twenty grains of calomel, and in half an hour twenty-five grains more. One hour after the first dose was taken, to my great pleasure I found the membrane was loosening and the cough and breathing improving.

The calomel was kept up in twenty-grain

doses every hour until four p. m., when he coughed up with great effort a piece of membrane about five or six inches long, and a complete mould of the trachea and one branch of the bronchi. Any amount of mucus was expectorated. Strange to say, with all this amount of calomel the bowels were acted upon only once, and that about 5 p. m. The patient passed a very comfortable night and continued in good condition until the evening of the 15th, when the membrane again commenced to form. On the morning of the 16th the boy was almost suffocated. I gave him now thirty grains every hour for five or six hours, and again found the little sufferer improving. In the afternoon complete moulds of membrane were brought up, and this raising continued until the 18th, by which time eight or nine complete moulds were raised, and any amount of shreds of membrane and mucus. During the intervals of severe oppression he took about five grains of calomel every four hours, and when the symptoms became more severe I gave him the large doses as frequently as the symptoms required.

At no time while he was taking these large doses of calomel did the action of the bowels amount to a diarrhœa, in fact part of the time there existed a constipated condition; all the power of the drug seemed to be used up in combating the effect of the disease, and to loosen the membrane large doses were required. At no time was an emetic employed, my reliance being upon calomel and steaming thoroughly the patient. The disease abated on the 18th, but the patient was left with a pneumonia involving the entire left lung, and the lower half of the right lung. The little fellow struggled through on the regulation treatment, but was left with complete anorexia; this in turn was combatted with rectal injections of milk and whisky every two hours, day and night. On the 3d day of January the temperature was 98.2°, pulse 80, respiration 20, air permeating both lungs, tongue clean and moist, bowels regular, expression good, and a favorable termination confidently looked for. About noon of this day he commenced to complain of severe frontal headache, and great restlessness during the afternoon. About 6.30 p. m. he wished to have his bowels moved, which accomplished, he asked to be put back in bed, and died almost instantly. What caused his death was and is a mystery to me. Was it heart-clot? If so, what, if anything, had the severe frontal headache to do with his sudden death? The treatment I am perfectly satisfied with in this case, but the result, I must say, was a shock and surprise to me.

Now I will take up the next case, which will not consume much of your time. The mother of the boy, aged 42 years, began on the 14th to complain of stiffness in the region of the throat, some difficulty in swallowing, hoarse voice, croupous breathing, elevated temperature, with slight deposit, noticeable on the tonsils. On the 16th, there was entire loss of voice, and all the symptoms increasing in severity. On the 18th, the temperature was 105°, respiration 40, pulse 150, cough ringing, and the membrane firmly adherent to the walls of the trachea and the bronchial tubes. She had been taking from five to ten grains of calomel every four hours for two or three days, and now the symptoms becoming so alarming, I increased the doses to thirty grains every four hours, when the membrane becoming detached was raised in distinct moulds, but not nearly as perfect as her son's. With the raising of the membrane the symptoms were ameliorated, but this was only of short duration. The morning of the 19th found her every symptom aggravated, and although I gave large doses of the calomel, it apparently had little or no effect. In the afternoon about 4 o'clock I was called, and found her almost suffocated; and succeeding in getting a large dose of tartar emetic down her, she vomited a solid piece of membrane from the upper part of the trachea and a large amount of mucus. I called my neighbor and friend, Dr. W. E. Doughty, to my assistance, with the object of performing tracheotomy if deemed advisable; but on account of the membrane being firmly fixed below where the tube should be inserted, the operation was not performed, and now all we could do amounted to nothing, and our patient died at 1 a. m. on the 20th, from complete asphyxia.

This was a most remarkable case, on account of the age of the patient. Dr. Gove Mitchell, forty years ago, said of this family that there was in the members of it when much sick a strong tendency to death, and this woman was always disposed to take her children's diseases. I do not think there can be any doubt but that the disease was true croup, on account of all the symptoms standing out in such bold relief. Having exposed my failures to the profession, I hope it may influence for good those who read the report. Still I believe that it is, in the present knowledge we possess, the best treatment extant.

J. B. Carrell, M. D.

Hatboro, Pa.

A CORRECTION.

Short Intervals Between Labor.

EDS. MED. AND SURG. REPORTER:

In the issue of this journal of February 6, 1886, is a report from Dr. L. N. Davis of a case reported by me to the Randolph County (Ind.) Medical Society—a case of two confinements at term within a period of nine and one-half months. Dr. Davis is correct, but I was wrong. The case was reported verbally from memory, and I find on examining the records that the time is ten months and eleven days, instead of nine months. The time, when corrected, still being so short, I append a report of the case, asking that those who have found a shorter time between confinements at term will report.

March 9, 1883, called to see Mrs. C., a primipara. Found her in convulsions, and after the usual remedies for their control and much patience were exhausted, I succeeded, with the aid of Dr. H., in delivering her by use of forceps of a child apparently still-born. However, breathing was finally established, and it lived three hours.

A second still-born child followed the first in a few minutes. This was followed immeately by the placenta, and this in turn by convulsions that had seemed to be under control. We again resorted to morphia hypodermically, which finally controlled them. In all she had about fifteen convulsions, remained unconscious for two days, and delirious most of the time for two weeks. Albumen remained in the urine in considerable quantity for five months.

On January 20, 1884, I again delivered her of a healthy female child, seemingly at full term. Mother and child at this time both did well. This is ten calendar months and eleven days, or 317 days, from her first terrible experience—she again passed through the ordeal, but this time with comparatively great ease. I. N. TRENT, M. D.

Losantville, Ind.

Ethylate of Sodium in Nævus.

EDS. MED. AND SURG. REPORTER:—

I see by the last REPORTER that one of your readers is anxious to know something about the treatment of nævus with the ethylate of sodium. I have not had a very extensive experience with it, but sufficient, I think, to warrant me in recommending it very highly. As prepared by Wyeth & Brother, it is a pasty liquid of about the consistency of cream. The following is the manner in which it is used: Take a piece of adhesive plaster, cut a hole in the centre of it the size of the nævus. Apply this over the nævus. This serves to protect the sound skin and leaves the nævus exposed for treatment. Paint the nævus on two successive days with the sodium, using a camel's-hair brush. An eschar is formed, which comes off in two or three weeks, and the nævus is cured. The pain from the application of this remedy is not very great, and the result is entirely satisfactory.

OSCAR LEEDOM, M. D.

Plymouth Meeting, Pa.

NEWS AND MISCELLANY.

The Naval Medical Society.

[Reported by FREDERICK HORNER, M. D.]

The thirty-seventh meeting of the Society was held on Thursday evening, February 4, 1886, at 8 o'clock, in the library of the Museum of Hygiene, at the corner of Eighteenth and G streets, Washington city. This building, once known as the "Edward Everett House," was once the residence of Mr. Jefferson Davis while Secretary of War. The Museum is an appendage to the Bureau of Medicine and Surgery of the Navy Department.

The Society continues to hold monthly meetings. President, T. I. Turner, U. S. Navy, and H. G. Beyer, M. D., U. S. N., Secretary. The attendance, though comparatively small, is usually honored by the presence of Surgeon-General F. M. Gunnell; I. Miles Brown, Medical Director; A. L. Gihon, the eminent sanitarian; H. G. Beyer, microscopist; Chas. H. White, chemist; C. H. H. Hall, biologist, and James M. Flint, connected with the U. S. Fish Commission, all surgeons of the U. S. Navy.

The following instructive and practical papers have been read at the various meetings:

1. Report on a case of dilatation of the heart, with post-mortem, by Dr. Chas. H. White, U. S. N.

2. Case of colitius with anomalous symptoms post-mortem, by Dr. C. H. H. Hall, U. S. N.

3. Sydenham and Hahnemann, by Dr. F. B. Stephenson, U. S. N.

4. Case of typhlitis and partial constriction of the bowel, followed by perforation, peritonitis, and death, by Dr. Oliver Diehl, U. S. N.

5. Case of enteric fever with pathological specimens, by Dr. A. L. Gihon, U. S. N.

6. Annual address of the retiring President, by Dr. T. I. Turner, U. S. N.

7. Report on the discovery by Dr. Lustgarten of the specific micro-organisms of syphilis, by Dr. H. G. Beyer, U. S. N.

8. A plea in behalf of a naval hospital for inebriates, by Dr. Frederick Horner, U. S. N.

9. The uses and dangers of antipyretics, by Dr. H. G. Beyer, U. S. N.

These monthly reunions of the surgeons of the Navy of the active and retired list are of the most pleasant character, socially and professionally. It is to be regretted that the publication of the *Transactions* has been for some time suspended. The annual report of the Surgeon-General furnishes valuable data, embracing the official reports, statistical, medical, and surgical, of the surgeons of the various naval squadrons and hospitals. The hope may be indulged that in the near future the powers that be will accord to the Naval Medical Staff like privileges enjoyed by Naval Cadets, and will establish a Naval Medical School, such as the English and French have at Hasler and at Marseilles.

It may be added that the Museum of Hygiene extends a cordial reception to visitors. As stated in a former notice, Surgeon I. Miles Brown is Superintendent. The plan on which the Museum is conducted comprehends, as the late report published in the *Sanitary News* says, "the collection of material which shall illustrate the entire scope of sanitation, the delivery of lectures by prominent sanitarians, and the maintenance of a library which has now 7,300 volumes, including standard sanitary books in the English, German, and French languages, accessible by all who are studying the subject."

Mr. Glenn Brown, architect, is engaged at present in making experiments illustrative of sanitary engineering, conducted on the rear outside of the museum building, from the ground to the roof, a distance of fifty feet, with an observing station and outlets for the attachment of traps and fixtures. Here an exhaustive series of experiments is being carried on, showing the effects of siphonage, ventilation, etc., and to determine questions in dispute, and to furnish data where data is wanting in this important part of house planning, and when completed must prove a valuable contribution to sanitary science.

Beware of Bogus Dentists.

In the *Am. Agriculturist* C. P. Dewey says that the operation of pulling teeth is not ordinarily regarded as an "entertainment," either by the dentist or his victim. Yet it was made so by a "professor" in Reading, Pa., who was arrested there a few days ago. He called himself a painless tooth extractor, and had a brass band and a variety singer, who acted as a popular allurement, and hundreds of people were enticed into the operating establishment and there induced to part with their teeth, and then with their money, for worthless medicine and more worthless advice. There is a class of traveling and advertising dentists who go about the country and practice their art upon credulous people, in ignorance of its principles, whose sufferings in the end are only heightened by the mistaken means they have taken for relief. The art of dentistry has made a great advance within a few years, and what was once deemed impossible is now easily accomplished. It is probable that the time is not distant, when to draw a tooth because it aches will be regarded as absurd as to lop off a finger because it is painful. Teeth are treated and "doctored" with as much system and success as any other part of the organization, and are preserved to a good old age as assuredly as an eye or an ear. But they must be examined and inspected by a competent dentist every year or two, to discover whether there are signs of decay, and to remove the deposits of tartar which may threaten them. Such an examination is simple and cheap, and saves much pain and cost in the end. Of course, no one should neglect the daily habit of using a tooth-brush, by which means the clinging particles of food and the minor accretions that disfigure the teeth are removed. Nothing adds more to the good looks of man or woman than well regulated teeth, and nothing is more unbecoming than a mouth with bad, or broken, or discolored teeth, the relics and ruins of what might have been ornamental and useful. It is a very great comfort to possess good teeth to the end of life, and the comfort is worth paying for. If properly taken in hand early in life, and when the first indications of decay appear, the teeth may be usually made secure for all time.

Disinfection by the Salt-water Stove.

A year ago Prof. A. Dobroslawin, of St. Petersburg, published a preliminary communication on a portable disinfecting stove constructed by him, which acted through overheated air. The author obtained the high temperature simply by the use of solutions of common salt instead of plain water. To produce a higher temperature some different

salts may be employed. In 100 parts of water, 41.2 parts of common salt gave the boiling point at 108.4° C.; 61.5 parts of nitrate of ammonia gave it at 121.0°; 205.0 parts of carbonate of potash, 135.0°; 325.0 parts of chloride of calcium, 179.5°; 88.9 parts of chloride of calcium, 114.2°. The stove requires from 40 to 50 litres of the solution, and boils with a solution of common salt after two or three hours. After four hours' working it must be refilled. To prove the effect on micro-organisms, silk threads saturated with the spores of bacillus subtilis were submitted to the stove, and were completely killed, after remaining three or four hours in the stove, at 102° to 104° C. The price of the apparatus is 250 roubles ($125), to be procured through the St. Petersburg Metallfabrik.

Injections into the Lungs.

A discussion has recently taken place in the Medical Society of the Paris Hospitals, chiefly between M. Gougenheim and M. Dieulafoy, on the advantage of practicing antiseptic injections into the tissues of the lungs in cases of phthisis. M. Gougenheim had injected bichloride of mercury in thirty-three cases of advanced phthisis with considerable amelioration, the loss of flesh being retarded, and the râles as also the expectoration diminished. M. Dieulafoy, on the other hand, had, in 1881, practiced injections of glycerine of carbolic acid, coloring this with cochineal, by which means he was able to assure himself by inspection of the sputa that the antiseptic had entered a cavity. He found, however, that the patients suffered great pain from the injections, and that no beneficial effects followed, so that he soon abandoned this treatment.

Quackery and Its Punishment in Holland.

A Rotterdam jeweler, who has been for some time past carrying on the trade of "cancer curer," which he seems to have found much more profitable than that to which he was brought up, has found to his chagrin that the Dutch laws do not allow of the perfect freedom in the treatment of the human body, which is doubtless considered as an important part of the liberty of the subject by the whole confraternity of charlatans. Had his impostures been carried on in this country, it is questionable whether he could have been successfully prosecuted at all, and under the most favorable circumstances he would only have been compelled to disgorge a few dollars of his ill-gotten gains by way of a fine. The Dutch court, however, marked its sense of the gravity of offenses of this character by sending him to prison for fifteen days.

Dr. E. O. Shakespeare.

Dr. E. O. Shakespeare, who was appointed by the President of the United States a special commissioner to visit the cholera districts of Europe and investigate the disease, after performing his mission commendably, is expected to return to us within the next two weeks brimful of valuable information.

A movement is on foot, headed by Dr. Levis, Dr. M. S. French, and other prominent members of the County Medical Society, looking to giving Dr. Shakespeare a suitable and certainly well-merited reception. It is expected that distinguished national, state, and municipal officers will take part in this deserved reception of our distinguished commissioner. We look forward eagerly for the valuable information which Dr. Shakespeare will bring us.

To Suppress Pleuro-pneumonia.

The Berks County Agricultural Society has decided to ask Congress to make an appropriation of $500,000 to be used in the suppression of pleuro-pneumonia. They suggest that this fund be drawn upon by the Governors of the States in the reimbursement of persons whose cattle may be destroyed by authorized agents in the effort to arrest the progress of the disease, and that a set of rules relative to the eradication of pleuro-pneumonia be prepared by the National Department of Agriculture, to be observed in all the States. Senator Cameron and Congressman Ermentrout will be asked to press the bill to passage.

An Important Invention.

A very important invention, which will, as is said by some lighting engineers, completely revolutionize the present system of gas-lighting, has just been perfected by Dr. Auer in the chemical laboratory of the Vienna University. Briefly described, the invention may be said to consist in rendering a cotton wick incombustible by impregnating it with a metallic liquid. Thus treated, the wick, instead of burning, merely glows, emitting a radiance not unlike that of the electric light. The whole process is very simple, and the great advantage of the invention is that it may be applied to any gas-burner.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED FEBRUARY 6, 1886.

Bennet, P. H., assistant surgeon. Died at Detroit, Michigan, February 3, 1886.

Watkins, R. B., assistant surgeon. To proceed to Detroit, Michigan, for duty, February 3, 1886.

Puttus, W. J., assistant surgeon. Appointed an assistant surgeon February 5, 1886. Assigned to duty at New Orleans, Louisiana, February 6, 1886.

Liquid Glue.

The following directions for preparing a glue we have found to be good, and we therefore give it to our readers from the *New England Medical Monthly:*

Fill the vessel (glass) with the best broken up glue, and fill up with acetic acid. Keep it in hot water for a few hours until the glue is melted, and you will have a most excellent glue always ready.

Personal.

—Dr. G. Betton Massey has removed to 1706 Walnut street.

Items.

—The Société de Médecine de Paris has awarded the Duparc prize, value 1200 francs, to M. Dalché, interne of the Paris hospitals, for his treatise on ovaritis.

—Dr. Filechne, teacher of Pharmacology in the University of Erlangen, has accepted an invitation to the professorship of the same subject in the University of Breslau, in the room of the late Dr. Haeser.

—It is announced that the city of Amsterdam will send Dr. Saltet, of the hygienic laboratory, to Paris, to study M. Pasteur's methods of inoculation for rabies. The expenses will be paid by the municipal funds.

—The progress of pharmaceutical education in America is being marked by the Massachusetts College of Pharmacy, which is erecting a much finer and more convenient building than has ever before been used for such purposes in the United States.

—An old man in Stoughton, Mass., described as "stalwart, robust, and vigorous," has bathed every morning for years in a cold spring near his house. The baths were not omitted recently when the thermometer was 18° below zero. He says the custom cured him of catarrh, and is the panacea for all ills.

—"My poor man," said the doctor, "you are dangerously ill. Is there any word you want to send to your friends?" "Am I really so ill?" asked the sufferer. "Alas? I can offer you no hope." "Very well, then," said the sick man, "just telephone for another doctor."

—The lively interest in dogs just now (or perhaps we should say the mortal fear of them) will give point to the instructive pages by Hugh Dalziel, in the March *Harper's*, on "Dogs and their Management." Advice from so eminent an authority concerning the proper care and treatment of canine pets will receive careful attention. Especially valuable are the particulars in regard to distempers and madness.

—Mr. Snell urges Opplus' method of concealing the smell of iodoform. It consists of mixing one part of freshly ground coffee with two parts of iodoform. The result is most satisfactory, it being difficult to detect the presence of the iodoform, and the effect lasts for a very considerable portion of the time, *i. e.*, three weeks or a month. The coffee is also accredited with antiseptic qualities.

—Rhodomyces, according to Dr. Wettstein, is a fungus closely allied to oïdium albicans, but differs in the appearance of the conidophores, the modes of formation of the conidia, and especially in its unseptated hyphal branches. The fungus was found in the fluids ejected by patients suffering from pyrosis. It presents itself as a dense, delicate pink growth, containing enormous numbers of conidia.

—A Polish physician, wishing a patient to be dry-cupped in eighteen places, wrote the order with the figure "18" followed by the letter "b," to stand for the Polish word for cups. This again was followed by the word meaning "dry." The dresser, mistaking the "b" for "6," actually practiced 186 dry cuppings on the unfortunate patient. The Russian journal from which we learn this incident remarks that it is well that it was dry and not wet cupping that was ordered.

—Dr. Bremer, at a meeting of the St Louis Medical Association, stated that he had seen a man with a peculiar form of melancholia. He thought that he emitted a horrible stench, that every one smelled him, etc. He had lately seen a young married man with confirmed melancholia who imagined the same thing. He went to the police station and stated that he was a corpse undergoing decomposition, and wished to be taken to the morgue. He eventually cut his throat.

JENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle, pleasantly flavored. Retail $1.00. All of it pure pepsin.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*

2d. *All materials weighed with scrupulous exactness.*

3d. *The mass sufficiently consistent to maintain the globular form, and yet readily soluble in the stomach.*

4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin*," must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also ammmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

Lecture.

RETROVERSION OF THE UTERUS.*

BY C. D. PALMER, M. D.,
Of Cincinnati,
Professor of Gynecology in the Medical College of Ohio.

One of the commonest forms of displacement of the uterus is retroversion. It is not *the* most common, for it is very probable that prolapsus in its various degrees is of the most frequent occurrence. I wish to-day to make some remarks concerning this most important uterine dislocation, not by any means attempting to go over the whole range of the subject, but to touch on some of the more salient features of the disease, in its etiology, diagnosis, and treatment.

Retroversion, or backward displacement of the uterus, in the great majority of instances, is found in multiparous women; (not invariably, for nulliparæ are sometimes so affected,) as a result of parturition and conditions present in the lying-in state.

All displacements of the uterus are brought about by whatever increases its bulk and weight, whatever relaxes its support, whatever presses it out of position, and, finally, whatever pulls it out of position.

These are the four factors, in the main, operative in creating all kinds of displacements; the special kind, prolapsus, anteversion, retroversion, or lateroversion, being dependent upon the degree or intensity, the direction or combination, of these causative forces.

Now, there is no time during the life of any woman when these factors are so frequently and potently operative as after parturition. At no time, unless from tumor, is the uterus bulkier and heavier than after delivery—even ten days to two weeks—the time when most women get up from the lying-in bed.

It takes from one to two months for the uterus to resume its normal size. Many circumstances—as injury to the soft parts by bruising or laceration, septic absorption, septic or non-septic inflammation, bad states of the general health—may delay these healthy, necessary, transforming changes in the uterus, and it remains an enlarged, heavy, very vascular organ, easily displaced, because of an incompetency of its supporting powers under an increased pressure. But, at this very time, the supports themselves are weakened. The vagina has recently been enormously stretched; it may be, torn. The perineum and the pelvic floor, which underlie the vaginal support, if not lacerated, may have been stretched. All the surrounding ligaments are relaxed—consequently weakened.

Under these circumstances you can readily appreciate how prone she is to a displacement of this organ. With perineal lacerations quite often do we find retroversion associated, directly or not, as cause and effect. The perineum may be torn back to and through the sphincter ani, and no displacement of any kind follow. None will follow unless other structures are at fault. These are an increased bulk of the uterus, and above all, a relaxed condition—a yielding of the pelvic floor. A firm, unyielding pelvic floor has more than aught else to do in maintaining the normal position of the uterus.

So much, then, for displacements in general. I will now refer to a few special causes which,

*Abstract of a clinical lecture before the class.

in conjunction with the above, are active in developing retroversion:

1. The posterior wall of the uterus after parturition is, usually, thicker and heavier than the anterior—a condition which, during the involution processes acting in the line of gravity, aids the organ to fall backwards.

2. The posture of the lying-in-woman. Usually, it is the dorsal, with the shoulders elevated, and the pelvic inclination so altered as to increase to the utmost the intra-abdominal and intra-pelvic pressure from above. This augments the blood supply in the hinder portion of the uterus, delaying involution there, and gives full play to the forces of gravitation in the backward direction.

3. The pernicious practice of adjusting an abdominal bandage with an underlying pad, tightened from day to day by the full strength of the nurse, while the patient is in the incumbent dorsal position.

4. Constipation—distension of the rectum with fæcal accumulation, together with the straining efforts at stool to effect rectal evacuation, further stretching the pelvic floor and the utero-sacral ligaments.

Many of the worst cases of retroversion and retroflexion are associated with lacerations of the cervix. This accident brings about sub-involution, and occurs very generally when labor has been tedious and painful, and other soft parts have suffered injury.

In the comparatively few cases in which retroversion is present before delivery, it is coupled with retroflexion, and is generally congenital. Such a displacement may give rise to no disturbance, excite no suspicion of its existence, until some complication arises.

When retroversion exists before any pregnancy, it usually gives rise to no great inconvenience in the first few months of utero-gestation, although the backward movement at first is increased; afterwards (4th month), it rectifies itself. But, almost invariably, the displacement repeats itself and is rather aggravated during the coming lying-in state, to which reference has just been made. At the same time, I know from personal experience, that this time is an especially auspicious one to treat any woman for retroversion, with a view to prevent, or favorably modify, the old trouble.

There is no symptom or group of symptoms which is constantly found; none upon which any dependence can be placed in determining either the existence or kind of displacement.

Symptoms may or may not be present. The worst cases sometimes, though rarely, produce no discomfort, create no symptoms; and vice versa, the greatest disturbance is at times noticeable when there is but a slight displacement. You may be surprised at this statement, but it is nevertheless true. The explanation lies in the fact that the symptoms do not arise so much from the *disorder of place*, as they do from the *disorder of circulation*, either antedating, co-existing, or following it.

There are many things with which retroversion can be confounded. Perhaps there is no more common mistake made in the diagnosis of female pelvic diseases than right here, in reference to conditions partly resembling retroversion. This displacement in its simplest form, uncomplicated, is very easy of recognition. The altered position of the cervix and the corpus uteri, the filling up of the posterior vaginal cul-de-sac with a rotund, hard body, which is usually movable, and capable of being dislodged by position and taxis: these are elements of diagnosis. But there are so many different diseases, as fibroid tumor, thickening of the posterior uterine wall from hyperplasia, chronic pelvic peritonitis, chronic pelvic cellutitis, pelvic hæmatocele in its after effects, extra-uterine pregnancy, etc., which create a like fullness and hardness to a certain degree, with or without a tenderness to touch behind the uterus, that by a little carelessness or ignorance, a mistake can easily be committed. Owing to imperfect histories and certain complications, such as the obscurities surrounding some cases, clearness in diagnosis is by no means easily reached. Some of these errors are much more frequently made than others. I know of none more so than the diagnosis of retroversion for chronic pelvic peritonitis, the uterine axis being normal, or nearly so—a very serious error so far as the welfare of the patient is concerned.

Before any treatment is instituted, the inquiry should be made: What has caused the displacement? Is the displacement the first disorder which has taken place in the case, or is the displacement but secondary to other conditions? Again, is the displacement complicated with other diseases?

The mere mechanical correction of the displacement may be a very improper treatment. Find out, if possible, what has been the primary link in the chain of the disease, and what is secondary, for almost invariably a number of conditions are linked together in a chain of morbid action, and the whole line is best broken up by taking hold of it in a certain order.

Retroversion, like the other uterine dis-

placements, is in most cases a secondary disease. It does not occur first as the result of an increased bulk and weight of this organ, coupled with some relaxation or weakening of its supports. In those exceptional instances in which the displacement is primary, it is doubtless the proper thing to do to correct it at once, by mechanical means, especially should there be resulting symptoms; but for reasons manifest in the great majority of cases, a different procedure is not only prudent but necessary, if we expect a permanent relief. For instance, if increased bulk and weight of the uterus are encountered with a displacement, correct the former first. The increased vascularity of the organ—a necessary accompaniment of increased bulk—is diminished by rest and leeching; better still, by puncturing, local applications of anhydrous glycerine, the hot douche, and occasional purgation. The long-continued effect of ergot in small doses changed in time to the administration of the mercuric bichloride in minute doses, is exceedingly beneficial. The bitter tonics, with nux vomica, are also very useful, improving the general and local circulation, and giving tone to locally relaxed parts. If the integrity of the parts—the perineum and pelvic floor—have not been too much destroyed by tearing or stretching, if the cervix uteri has not been much torn, so that a radical change in the structures of the uterus cannot be effected without a resort to operative measures, the means mentioned will often so improve the local condition of the uterus and the surroundings that the retroversion is either entirely corrected or so far improved that no special attention to it is required, and no further treatment is needed. In my own experience, this plan has so often succeeded in correcting or diminishing retroversion that I generally commence a course of treatment in this way. Should the perineum, however, have been much lacerated, the vaginal walls relaxed and displaced, the cervix torn, everted, and enlarged, an improvement can proceed only to a limited extent unless surgical steps are taken to repair damages.

The restoration of a lacerated cervix uteri to its normal shape, size, and circulation, by trachelorraphy, will have very much to do in improving the position of a malposed uterus. The repair of a torn, weakened perineum and vaginal walls, by perineorraphy and colporraphy, is generally absolutely necessary to bring about any decided and permanent change for the better in the position of the uterus.

Now, these and all other complications and antecedent conditions having received due consideration, we are ready to give the retroversion itself attention, provided it persists, and provided, also, it creates no discomfort, and does not interfere with the circulation or function of the surrounding parts and organs.

Now, as to mechanical supports. Before we think of them, we should see whether we cannot diminish pressure from above. With this object in view, the clothes should be tight and suspended from the shoulders. The bowels must be kept free from fæcal and gaseous accumulation. It is highly absurd to attempt to prop up from below a displaced uterus, when it is pushed down by avoidable pressure from above. No abdominal bandage can be of any service in pure retroversion. The uterus cannot be lifted up by abdominal appliances; the most they can do is to lift off, to a limited degree, the intra-abdominal weight. The intra-vaginal supports are pessaries and tampons. The former may be called permanent, the latter temporary supports or splints to the dislocations. The former should never be utilized until the dislocated organ has been put beforehand into the best possible condition, by healing any erosions, checking catarrhs, diminishing weight, and strengthening the surroundings. Not so with the temporary support; for its use each time before insertion does not imply a complete rectification of the mal-position. With the tampon properly constructed, medicated, and placed, we have a means not only to temporarily hold the mal-posed organ *in situ*, but to alter its circulation and structure and remove its diseases. Its effects, then, are mechanical and medicinal. Many displacements are best treated by them at first; some need no other treatment. It requires some skill, acquired only by experience, to obtain their full benefits. In the displacement under consideration, after the uterus has been replaced (if possible) by posture and taxis, a broad, flat tampon made from absorbent cotton, saturated with an emollient or astringent lotion, as the case may require, is packed in the posterior vaginal cul-de-sac, to suspend the uterine body, and draw back the cervix; while another is packed in the anterior cul-de-sac to assist in the same movement. Treatment of this kind, repeated at intervals of once in three days, continued for several weeks or longer, accomplishes a great deal of good. In conjunction with the use of a vaginal douche during the intervals, and appropriate general medication, it may be all that is required. Repeated reposition, al-

ways gently made, and well-nigh continual support with the tampons, gradually do away with the structural faults in the uterus itself, enable the natural supports to regain their former strength, and bring about a return to normal position, which may be permanent.

I think very highly of this class of treatment in cases of retroversion, with or without flexion, in which from long-continued malposition or otherwise, the uterus has become fixed by adhesions to the rectum, and immediate reposition (unless great force is employed) is impossible. The repeated use of these tampons, continued for some time, will, by degrees, soften the para-metritic adhesions, put them on stretch, break them down in a way which is perfectly safe, and gradually make the uterus mobile and reducible. Yet how often we see patients so afflicted treated by a pessary! Would it not be just as rational to apply a splint to a non-reduced fractured bone?

A word as to the use of the sound to reduce dislocations of the uterus. The sound should not be used if we can possibly succeed in replacing by posture and taxis. The sound should not be used if there is the least suspicion of pregnancy. Careful inquiry should always be made in reference to the menstrual history. It is practicable to reduce any dislocation of the uterus, even when adherent, it matters not how long standing; but it is not prudent to do so. The practice is hazardous. It is by far a better plan to gradually stretch and soften the adhesions, as before suggested, than to resort to force. But there are cases and conditions suitable for the employment of this instrument. When posture and taxis have failed, and when the uterus is impacted under the promontory of the sacrum, but is not tender to touch, and will bear the manipulation, then we may carefully use the sound. I prefer it to all those contrivances which are called uterine repositors. The following is the method: Introduce the instrument properly curved within the uterus to the fundus. Change the relation of the concavity and convexity of the shank by rotating the sound, not by suddenly twisting the uterus upon itself, but by keeping the uterine extremity as stationary as possible, and revolving the manual extremity over an arc of 180°, the sweep of which is as large as the vagina and vulva will permit. When done, depress the handle against the perineum. By this method there is little or no injury done the uterus, and hence a minimum of pain.

We cannot dispense with pessaries in the management of some displacements, principally retroversion. They are a necessary evil. Properly constructed, accurately adjusted, in well-selected cases and conditions, they are capable of giving great comfort, and doing much good. To a very great extent the bad repute in which they have been held by some, is owing to their misuse.

The class was then shown three cases of retroversion, their histories read, and treatment given.

Communications.

PYÆMIA OR BLOOD-POISONING.

BY CHAS. P. KING, M. D.,
Of Newark, O.

The subject to which I invite your attention for a short time is that of pyæmia or blood-poisoning, and in presenting this paper for your consideration, I beg leave at the outset to ask your kindest indulgence for its deficiencies, on account of the shortness of time allowed me for its preparation. The subject is one of exceeding interest, the literature of which is both rich and extensive.

It would be pleasant to present you with a full and comprehensive resume of it in numerous and valuable studies, but the character of this paper forbids.

The fact that some injuries and operations are occasionally followed by the development of abscesses in some one or more of the internal organs of the body was brought to the attention of some of our older surgeons. The subcutaneous tissue and joints are the most frequent seats of these abscesses. Sometimes they affect the lungs and other viscera. Ambrose Paré, the great French surgeon, makes mention of it, and his observations were afterwards confirmed by those of Morgaigne, Larry, Guthrie, and other military surgeons of continental Europe. Velpeau, however, was the first surgeon we have any knowledge of who investigated the lesion in a really scientific manner, and who turned the attention of the profession to a most thorough and elaborate examination into its etiology, pathology, and treatment.

These observations were given to the world in 1823, a little more than half a century ago. Previous to that time but little was known as to its real pathology.

Pyæmia literally means pus in the blood, or in other words, a condition in which there are pus-cells in the blood; but the expression is known and now considered as imply-

ing that the blood is altered throughout the whole system by the previous action of putrid animal substance in the form of gases, fluids, or solid particles, which so distort its relations with the living tissues as to induce coagulation of the fibrin of the blood, in some part during life, within the blood-vessels, associated with fever and the formation of local abscesses in one or more of the viscera and other parts, and usually accompanied with phlebitis.

How then, the question may be asked, does pus enter the blood, and what is its physiological action upon the tissues? It will be my purpose to endeavor to answer the above question in the further discussion of this subject.

Pus as pus is never taken up or absorbed into the system. Its fluid parts only may be absorbed by the veins and lymphatics, but the solid portion remains as a thick, concrete mass, and thus the absorbtion or disappearance of an abscess gives rise to such "cheesy" products as are described by the name of "*tubercle*." Again, pus may be completely absorbed, but only after the cells have been reduced to a state of milkinesss by fatty degeneration, and become converted into an emulsive mass. The composition of pus varies very much, and the conditions under which it varies have not received that attention which its importance demands. It seems to vary with the locality whence it comes and the circumstances under which it is formed. Says Prof. Aitken, "Pyæmia as a specific original entity, a result of absorption of pus as such, is not now believed in, and any evidence of such an event daily becomes less and less."

Pyæmia is now regarded as a collective name for many different diseased processes, just as the essential phenomena of Bright's disease are brought about by several different morbid conditions of the kidneys. Hence the word pyæmia literally signifies, according to one of our most modern authors, "An alteration of the blood by pus, or perhaps, more properly speaking, by admixture of the two fluids, giving rise to what has been called septicæmia or purulent infection."

"Absorption of pus as pus" through the walls of the blood-vessels having been shown to be impossible on account of its cellular nature, the pus-cells being too large to pass through the capillaries, other theories are now advanced. Under the name of pyæmia several affections are included:

1. Septicæmia, that is, blood contamination from absorption in a liquid state of putrescent or otherwise morbific material.

2. Transfer of actual pus by veins in case of phlebitis, and its deposit in new localities.

3. Thrombosis, or coagulation, in a vein during life, followed by embolism, or the conveyance of a portion or portions of coagula, to different parts of the body, causing irritation and obstruction.

The exciting causes of pyæmia or blood poisoning are numerous and varied in their character. They may be stated in general terms to be such as are productive of great shock to the system, loss of blood, and depresssion of the vital powers.

The symptoms of this disease are chills, profuse sweats, low fever, rapidity and feebleness of pulse, great prostration, debility, and swelling of the joints. Death may occur in a few days from devitalization of the blood. The symptoms may be of gradual development, but oftener they set in suddenly with a chill, to which fever of a low type soon succeeds. The prognosis of this malady is most unfavorable; few cases recover, and these, for the most part, remain in a debilitated condition, liable to attacks of disease from the slightest cause. Of over forty cases, mostly gun-shot fractures, treated at one of the leading hospitals after the battle of Gettysburg, *all* died. During a practice of some seventeen years I have seen but four genuine cases of pyæmia, or blood-poisoning, all of which proved fatal. Death in these cases usually occurs within a week or ten days after the commencement of the malady.

As to the real nature of the poison of pyæmia, we know comparatively nothing. We only know it by its effects upon the human body. The poison, whatever it may be, is most virulent in its character, and it is one of the worst foes the surgeon has to contend with in his treatment of certain kinds of wounds. That certain constitutions are predisposed to it, is unquestionable, as it follows in some injuries of a most trivial character; this fact was demonstrated during our late civil war. I would like to discuss at length the various theories advanced by pathologists as to the manner in which pus is absorbed into the blood, but the scope of this paper forbids.

The doctrine advanced by the eminent Prof. Bennett, of Edinburgh, is probably the one now accepted by the profession at large. He accounts for the formation of purulent deposits by supposing that they are caused by the development of a peculiar poison derived from certain kinds of pus, which entering the blood, contaminates the circula-

tion and solids, and thus brings about that atonic condition of the system so characteristic of pyæmia. According to this doctrine, pus corpuscles do not enter and mingle with the blood; what has been taken for these bodies by various observers being the colorless cells of the blood, the distinction between the two being often extremely difficult, if not impracticable. Says the eminent Prof. Gross in his immortal work on surgery: "Agreeing with its advocates that it is impossible for pus corpuscles as such to enter the blood, except in the case of open-mouthed veins, communicating with a suppurating surface, I think it perfectly certain that the more attenuating and watery parts of pus, or, perhaps, more commonly speaking, the more ichorous, sanious, or sanguinolent varieties of this fluid, become commingled with the blood in suppurating wounds, and in the stumps of amputated limbs, thereby speedily and thoroughly contaminating both solids and fluids, and consequently effectually undermining the constitution, thus resulting in pyæmia or blood-poisoning."

Treatment.—As to the treatment of pyæmia but little need be said. Since the introduction of antiseptics in surgery by the eminent Professor Lister, of London, the death-rate from capital operations has been very materially diminished. Blood-poisoning arising from altered secretions in the wound, which has hitherto been the ever present dread and danger, is prevented. If this is owing to putrefaction, which depends upon the admission to the wound of the minute living particles, and if by the careful application of certain precautions these changes and their consequences may be with certainty prevented, then all these various forms of septic and pyæmic processes may and should be eradicated. This broad antiseptic method gives scope to a great variety of detail, which I hope to consider at some future time. Among the best known antiseptics are carbolic acid, salicylic acid, thymol, bichloride of mercury, and Listerine.*

In our treatment of blood-poisoning support and depuration of the blood are the main indications; of medicines, many have been advocated, but the profession have been disappointed in their results. Of these, we might mention the sulphates and hyposulphites of lime and soda, magnesia, and carbolic acid as an antiseptic. Dr. Bell, of Edinburgh, reports three recoveries with hardly any remedies. He gave milk, with lime-water, eggs, and beef-tea at short intervals. A general supporting treatment is indicated in every case. Quinine in large doses is advocated by some, and no doubt will do good in some cases. Dr. John Wood advocates saturating the air around the patient with carbolic acid by hanging materials containing it near the patient. This plan was carried out in the case of the lamented President Garfield. This is an admirable remedy where the patient is confined in a close room, where the air is not fresh and pure. Good nursing and attention to the surroundings of the patient are very essential. Disinfectants should be used from the very commencement of the attack. The eminent Dr. Paget says: "The exposure of the patient to currents of fresh air is most promising of success in cases of pyæmia."

The treatment of this disease is much better understood than formerly, and as a result the death-rate has been somewhat diminished.

Notwithstanding all this, we have yet much to learn as to the true nature of this disease, and until the pathology of pyæmia is much better understood than it is at the present time, it will continue to be, in the future as in the past, one of the worst foes with which the modern surgeon has to contend. In the light of the present century, when such rapid strides are being made in almost every department of science, we have every reason to hope at least that ere another decade shall have elapsed, some more subtle power even than the microscope will have been discovered, which will give us the power of scrutinizing more closely diseased conditions, and of finding out the agents which are so stealthily at work bringing the human machine to misery and premature death.

*At a recent meeting of the Philadelphia Academy of Surgery, Dr. R. J. Levis, of that city, read a communication entitled "New Antiseptics, Hydronaphthol, and Potassio-Mercuric Iodide." The claims made for the newly-discovered antiseptic hydronaphthol are that it is at least twelve times as effective as carbolic acid, thirty times as potent as salicylic acid, sixty times as effectual as boracic acid, and has six hundred times the antiseptic power of alcohol. As an antiseptic, it ranks next in importance to the mercuric bichloride. The potassio-mercuric iodide is four or five times as powerful as a true germicide or disinfectant as the mercuric bichloride. For such use it is effective in aqueous solutions in the proportion of only one to twelve thousand. The introduction into surgical practice of these two powerful substances will do much to overcome some of the objections and inconveniences of antiseptic practice. The profession owes a lasting debt of gratitude to Dr. Levis for having brought this subject to their notice in so practical a manner. Bisulphate of carbon, Pasteur, the great French scientist, thinks will become the most efficacious of all antiseptics, as it is also the cheapest, costing but a fraction of a penny per pound in large quantities. It is besides the best insecticide known, and for this purpose it is thought may be useful in preserving wood-work in tropical countries. Some idea of the use of it may be gathered from the fact that more than eight million pounds of the substance are sent annually to check the ravages of phylloxera. Bisulphate of carbon is produced through an offensive compound in respect to odor, but is capable of purification.

THE INFLATION OF THE EUSTACHIAN TUBE IN AURAL CATARRH OF YOUNG CHILDREN.*

BY LAURENCE TURNBULL, M. D.,
Aural Surgeon Jefferson Medical College Hospital, Phila.

In reply to a letter desiring to be informed as to the mode of the use of a tube to inflate the Eustachian tube by the mother, I must first state that her physician must be sure that the cause of deafness is an exudation of pus, mucus, or serum into the middle ear. If the child has had an earache, and there has been a perforation of the membrana tympani shown by a discharge, in this case the simple act of blowing the nose will open the tube; this act should always be taught the child.

If the child is too young to perform this, the nose must be cleansed several times a day with a soft camel's-hair brush, or small syringe and warm water, with a few grains of bicarbonate of soda, that will assist in opening the tube. If, however, there has been inflammation of the middle ear of the child, the result of a cold from a naso-pharyngeal catarrh, acute exanthema, or pneumonia, attended with pain in the ear, or if the acute symptoms have been relieved by leeching, hot water applications, chloroform vapor, etc., the child recovers without perforation, but is deaf. This deafness is apt to be overlooked in the beginning, even by the parents, and the child is sent to school, where even a very moderate degree of deafness is very soon detected, and the child is stated to be absent-minded, or has the bad habit of asking twice the same thing.

This inattention is very often due to an abundant secretion behind the drum membrane and the closure of the tube. There may be no very decided pain in the ear, but only a heavy feeling in the region of the ear or in the head in general. (We cannot at this time enter into the diagnosis and treatment of acute and chronic aural catarrh, but would refer those who are interested to chapter iv. of our work, under the title of "Artificial Perforation of the Membrana Tympani, and the Removal of Organized Material from the Middle Ear.")† This secretion is usually liquid or semi-solid, and if it has remained for a long time becomes dry. We must provide an outlet for it, and one of the quickest is paracentesis of the drum-membrane; but this is only necessary in severe scarlet fever or diphtheria and in older children.

We have in Politzer's inflation a valuable means of diagnosis and treatment, by which we can determine if there is fluid in the middle ear by placing the diagnostic tube in the child's ear, while we inflate through the nose and listen for the thud or normal or abnormal moist sound: this latter will make the diagnosis certain. This operation of Politzer's consists in a condensation of the air in the naso-pharynx, by a strong inflation into the cavity, while the nostrils are closed with the fingers. In the case of adults, it is necessary that they should at the same time swallow, in order that the raised palate may close the naso-pharynx behind, and also because the act of swallowing opens the Eustachian tube, and thus furnishes a passage of air into the middle ear. In children, however, this swallowing is not absolutely necessary, because the naso-pharynx is so small that the condensation of the air is greater than in adults, and because also the tubes are in children relatively wider than in adults, and the action of the compressed air can therefore more readily reach the ear.

Children in whom this method of inflation is employed, as a rule, contract the muscles, and so unconsciously raise the palate. Instead of the rubber bag for the air, as is generally used, with hard long nozzle to be inserted back into the nose, a short rubber tube is what I use, the two ends of which are furnished with a quill, bone, or ivory termination, one for the mouth of the physician, nurse, or mother, the other for the nose of the patient. After cleansing the nose by gently blowing, washing, or wiping it out, the end is inserted and kept in place with the finger and thumb, and with the other end a blast of warm air is blown into the middle ear. At first the little patient is frightened, and grasps both at the instrument and ear; but after a time he gradually becomes accustomed to it, as it gives no real pain, and it becomes rather a source of amusement. Any intelligent mother or nurse could practice this operation when so ordered.

1502 *Walnut st., Phila., Feb.* 22, 1886.

HOSPITAL REPORTS.

PHILADELPHIA HOSPITAL.

SERVICE OF DR. L. W. STEINBACH.

Hydrocele.

Feb. 10. These apparently trivial cases are really those which you will most frequently be called upon to treat, hence it is well that you should see them. This man came into

the hospital two days ago, and you see that he has a very large scrotum; it is in fact a hydrocele, which I will evacuate and inject the sac with carbolic acid, which I prefer to the tincture of iodine. The acid quickly benumbs the part, and a moment after the injection the patient feels no pain. Before injecting the acid, you will note that I smear the whole scrotum about the site to be punctured with cosmoline; this I do because if I did not take this precaution, and any of the acid should drop on the scrotum, it would burn it quite severely. I make it a rule to let these patients go about immediately after the injection, but confining them to bed on the second or third day, when the induced inflammation sets in, for exercise, at this time, may cause an undue degree of inflammation. I use pure carbolic acid, simply the deliquesced crystals, injecting from one to two scruples. Before injecting I grasp the scrotum and render it tense by pressure; then I lay my trocar and canula along the course of my index finger, and by a rotatory motion work the trocar in. You must always look out that you do not wound the testicle. I make it a rule when the accumulation is very large to evacuate it, allow it to re-accumulate, and evacuate again before I make the injection of carbolic acid, because by this means the surface to be cauterized is considerably reduced in extent. Now, when I have withdrawn the fluid I find the testicle large and hard, and upon inquiry I find that the young man had gonorrhœa some years ago; this condition does not, however, contra-indicate the injection of carbolic acid. When I have injected, I endeavor by manipulation to bring the acid thoroughly into contact with the tunica vaginalis; the pain, as I have said, is only momentary.

Stricture of the Rectum.

This girl, Eva F., is twenty-four years old; she is married, has had two children and no miscarriages, and says she has leucorrhœa, but has never had syphilis. She has been a drinking woman, but was perfectly well until October, 1883, at which time she suffered from diarrhœa, tormina, and tenesmus; she experienced great pain with each act of defecation, and suffered from headache and backache. Upon examination we found that she had a stricture of the rectum, which was located just a short distance within the sphincter. The fæcal discharges are thin, watery and offensive. When a patient complains of diarrhœa, dysentery or constipation, which persists without a good cause, you should always examine the rectum; it is a false modesty that holds us back from making these examinations. There is an expression of countenance that is somewhat peculiar to disease of the rectum, and that should cause us to suspect its existence; I might speak of it as an expression of great distress. When we find a stricture low down in females, it may be due to the extension of an inflammation from specific sores, causing a sub-mucous deposit and contraction. Epithelioma is not an uncommon cause, especially when we find the stricture about a finger's length within the sphincter. Simple ulcers or pelvic cellulitis may also serve as a cause, but cancer is the most common cause. Well now, when we proceed to dilate these strictures, the Sims' position is the best, the knee-chest position, but we can manage very well if she lies on her side. You see, before introducing my finger into the rectum, I fill the space between the finger and the nail with soap, which is a practical little point well worthy of your attention. It prevents the risk of wounding the bowel with the nail, and at the same time saves you from the danger of infection. When we find the anus patulous, as it is here, we are likely to find the stricture some distance above the anus; now, when I introduce the finger as far as I can, I find a simple narrowing of the calibre of the gut, but I do not feel any nodules or any exudation; the stricture is not tight. In these cases, when taken hold of early, something very like a cure can be effected by gradual dilatation; if not seen until late, the condition may be palliated, but we cannot hope to do as much as when we see them early. This woman's fæces are tape-like, and we should keep them soluble. The digestive system always suffers more or less in these conditions, and this derangement must be attended to. Remember, when introducing your dilators, the direction of the rectum, and always pass them from behind forwards, being careful never to use any force. This insrument, as you see, passes up readily, so I know that there is no stricture beyond that which I can reach with my finger, therefore I feel that this is a promising case. I am here using soft flexible bougies; some prefer using candles.

February 17. I wish to show you the case of hydrocele, upon which I operated last Wednesday. Now I feel a hard, irregular, nodulated swelling, which is due to the effusion of lymph, caused by the injection of carbolic acid. In time this will disappear and we will have the scrotum of its normal size. I would say that, as a rule, it will take about two months for this effusion to disappear.

Burn.

Here we have a burn that occurred nine weeks ago, and you see this granulating tissue; there are gelatinous masses with vessels around them—this is embryonic tissue; then we have formed cicatricial tissue, which is another step in the process of granulation; the embryonic cells become connective tissue cells—and cicatrization, remember, always commences at the edge of a wounded surface. These granulations are too large and florid, and bleed very easily; so I am going to hasten the healing process here by skin-grafting. It is always a wise precaution to take the grafts from the individual, as by so doing we avoid any possibility of infection. When skin-grafting first came into vogue, large pieces of skin were used, but it was subsequently found that they did no better than small ones. After a while the epiderm macerates off from these grafts, and unless you are prepared for this you may imagine that your grafts are not going to take; but the true derm remains, and this is all you want. Now I take an ordinary cambric needle and transfix the smallest possible piece of skin on the arm with it; then I pass scissors under the needle and nip off this minute piece of skin; I am careful to get the under surface of the graft applied to the ulcer. In former times it was the custom to make incisions on the surface before applying the graft, but it was found that the blood so drawn was really an impediment to the success of the operation, and it was abandoned. After placing these grafts in position I will allow the surface to remain exposed for an hour, so that the plasma exuded may fix them in position before I apply any dressing. After several days, if the grafts take, I will note a slight blue pellicle. It is, of course, possible that none of these grafts may take, or it may be that some will take and others will fail.

Fistula in Ano.

My experience tells me that this condition is most common in those of a strumous diathesis. You may have an inflammation of the glands about the rectum, and when the discharge comes exteriorly, and also from the anus, it may be the first indication you have of a fistula. The usual seat of the internal opening of a fistula is just within the anus, near the margin of the junction of the skin and mucous membrane; this is an important point to remember, because the inner opening is not infrequently overlooked, because it is looked for too high up. When deciding upon an operation for fistula, I would say that we should never use the ligature; incision is not dangerous, and is nearly always successful. Sometimes, when we have multiple external openings, we must lay them all into one.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

Service of D. Hayes Agnew, M. D.

Sarcoma.

This patient I have only seen since he came in a short time ago. He is forty-four years old, and says that two years ago he first noticed a little swelling on his right side; that is, he first commenced to experience discomfort from it at that time, though it may have existed before. Such is the history we not infrequently get of carcinoma of the breast, the disease no doubt existing for some time prior to the date at which it first attracted attention. This swelling is oblong and seems to occupy about half of the abdominal cavity; the abdominal walls are resistant, and upon percussion I get very little resonance. He is losing flesh, suffers much pain, and has a cough. Upon examination I find a little trouble at the apex of the left lung. Grossly speaking, the urinary secretion is normal. Posteriorly there seems to be no evidence of trouble that I could refer to the kidneys, but I caution you always to look very carefully before you commit yourself to such an opinion. Renal cysts will offer a condition very much like this, only that they will not be quite so hard. Judging from the age of the patient, the rapidity of growth of the tumor, the cough, and the loss of the flesh, I would infer that this is a sarcoma. Of course, in such a case, an operation is not to be thought of; we can only look to endeavoring to improve the man's general condition. I would suppose that this sarcoma was located in the right iliac fossa.

Inverted Toe-nail.

The next case is of an apparently trivial nature, yet it is well that you should know how to intelligently manage such a case. Inverted toe-nails are of very frequent occurrence; it is not truly that the nail grows into the flesh, but owing to some irritation there is an inflammation and proliferation of the soft tissues, which then bulge up around the nail and bury it. Want of cleanliness will act as a cause, the dead epithelium remaining about the toe acting as an irritant, but it is most frequently caused by a bad-fitting shoe. So also the majority of persons cut the nails wrong; it is a mistake to round off the corners—the nail should be cut

squarely across. Now I desired to show you this case because I think in the very large majority of cases a mistake is made when the nail is removed; there is scarcely any case that cannot be relieved by patience and perseverance; by patiently inserting some lint or cotton beneath the nail and patiently making pressure on the elevated skin so as to reduce it. Of course, there are some cases where this cannot be done and where we must remove the nail. The case before us is one in point; here the nail disables the young man for work, and he cannot afford to take the time to lay off from work for the conservative treatment. I consider this to be the most painful operation in surgery, hence you must always etherize the patient. When the patient is thoroughly anæsthetized, I take a probe-pointed curette, and with it separate the matrix from the nail, when, with a pair of forceps, I draw it out. Sometimes, when the nail clings very tightly, it may be necessary to split it before we can remove it. After the nail has been removed, we will cover the raw surfaces with oiled lint or poultices for two days, after which we can use any kind of an ointment. Another nail, growing in place of the one removed, will be very apt to assume the same deformity as its predecessor, hence we must be very careful from the first to obviate the cause. Sometimes when the nail has been very greatly deformed, it may be well to destroy the matrix, so that another will not grow; when we wish to do this, we can pare around and cut out the matrix, and then apply caustic potash and dress with carbolized lint. In this latter event, a dense fibrous tissue will take the place of the nail, and will serve as a very fair covering for the toe. When you intend to save the nail, take a flat probe, and commencing at one edge, gradually work cotton under the nail, then make pressure on the flesh by means of a compress and adhesive plaster. I am frequently in the habit of making this compression with a piece of cork cut wedge-shape. I say, therefore, that it is only in exceptional cases that you are justified in removing the nail.

Senile Purpura.

You will occasionally encounter persons who will present a mottled appearance of the legs and feet, always in advanced life. They will be purplish, and there will be an indefinite dusky redness. There is no ulceration and nothing wrong with the kidneys in this case, which is a point to be noted, because such eruptions are not uncommon in persons suffering from Bright's disease or diabetes. But, though there may be no ulceration, there is usually some change in the arteries; they are atheromatous, and are, in consequence, disqualified from properly regulating the circulation, so that these vessels become unnaturally distended and a slight leakage occurs from them into the cellular tissue. It is really more than an œdema, it is an escape of lymph, which becomes more or less organized. This condition will sometimes cause great suffering in old persons, and will call for remedy. We must keep up the strength of the circulation in such cases, by giving carbonate of ammonia, and support the limb by an elastic stocking or roller. This will cause some absorption, but we must be careful to remove the bandage each day, because it will cause a sweating that, if confined, may irritate the part. This leg, I am quite sure, will look better in one week, under this treatment. These cases sometimes terminate in gangrene.

Adenoma.

This man has some kind of an enlargement behind his little finger on the left hand. He says that it dates back for only three or four months, but I think he must have had it for a longer time. You have seen bursæ on tendons, the contents of which is so much like calves-foot jelly. These bursæ are not common in this situation; I am not sure that it is a ganglion, but I think it is, for other kinds of tumors are rarely found on tendons. The consistency of this swelling warrants me in removing it with antiseptic precautions. Remember that the sheaths of tendons are very intolerant to interference, especially to open operations, so that, insignificant though the operation may seem, we will keep this patient in the hospital and dress his wound here. Now, when I remove it, I find that it is not a bursa, it is a solid tumor, made up largely of fibrous tissue and fat. I removed it without opening the sheath of the tendon; it was fed by one artery, which I ligate. This is an unusual location for an adenoma.

Service of Dr. John Ashhurst.

Green-Stick Fracture.

Here is a boy who fell down stairs and sustained a green-stick fracture of the forearm. The fibres of the ulnar on one side are broken, but not on the other. You know that this term is derived from the resemblance which such fractures bear to the condition of a green limb of a tree when you break it. All fractures begin in the line of extension, to use a term employed by

mechanics, the line of flexion is where the blow is struck. As I say, the fracture begins in the line of extension, and if the force has been great enough the fracture extends through the bone, but if not strong enough, it only extends through the line of extension. These partial fractures are apt to be overlooked, not so often in the forearm, but quite frequently when they affect the clavicle. A child may fall and strike on the shoulder. No symptoms are presented save pain when the neck is touched or moved, and, possibly, some slight depression. It may be supposed to be only a bruise, while in reality the clavicle may be broken. It is important that we should look carefully for such fractures, for if we do not recognize them, the chances are that they will be made out later on, and this discovery will not redound to our credit. Some authorities advise us to make gentle pressure in these cases of green-stick fracture, and leave the rest to nature; but I have seen considerable deformity result from this practice, and I think it is better surgery to convert the partial into a complete fracture by forcibly straightening the limb. I think it is best in all fractures of the radius, save in Colles' fracture, to use two straight splints. They should be long, commencing below the end of the elbow and extending to below the ends of the fingers. The posterior splint need not be so long, extending from below the olecranon to the back of the hand. If the long posterior splint is applied very tightly, it will cause pain and excoriation, but if you do not apply it rather tightly, it will be bulky and will be apt to lose its place. Be careful not to have these splints too wide; this is a very common mistake. I do not think it is necessary to use an interosseous pad. In all fractures of the radius it is of importance, in view of the future usefulness of the arm, that it should be kept in a supine position while the reparative process is going on. This point is not enough noted. If the arm is left straight, or, still worse, in a prone position, it will be found that when the fracture has united the power of supinating the arm has been lost. Such an arm as that before us should be kept in splints for at least three or four weeks. You had better err on the side of caution, for it would be very embarrassing to have the same bone refractured shortly after you had taken it out of the splints.

Fistula.

You know, of course, that you may have complete or blind fistulæ, but in either case you must lay them open. Fistulæ are most commonly caused from injury, though they may result from cold, causing an abscess. Accumulations of fæcal matter are very likely to cause internal fistulæ that have no external opening, especially if with the accumulation there be associated a stricture of the rectum. We may have a stricture of the rectum sufficiently open to admit the finger or a bougie, yet it will cause trouble by interfering with the peristaltic action of the bowel. That the bowels may be properly evacuated, just as with the emptying of the bladder, there must be a consensus of action on the part of all the muscles employed therein, and a stricture will interfere with this harmony of action. Well, then, this accumulation will irritate the mucous membrane, an abscess will form, and a fistula will result. When you find a number of fistulæ, you have a right to suspect some underlying condition, as a stricture. Again, when you find a stricture, always look above it for the internal opening of the fistula. When we have a stricture, we cannot hope for a perfect and permanent cure of the fistula unless we relieve the stricture. It is a serious and troublesome complication, but does not render the case necessarily hopeless. In some cases, when it is low down, we may divide the stricture, using the galvano-cautery, the knife, or the actual cautery, or we may cut the fistula and gradually dilate the stricture. To cut the stricture. I must caution you, it must be low down; it would not be safe to do so if it were high up.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Continued from page* 273.)

Another cause of tardy first stage of labor is

Premature Rupture of the Membranes.

This accident is apt to interfere with the progress of labor in the stage of dilatation by the absence of the dilating cone formed by the membranes in normal cases, and by direct contact of the presenting part of the fœtus with the uterus. Owing to the former, the uterine force is exerted at a disadvantage; and by the latter, the os is apt to become rigid, dry, and sensitive, while the mother's suffering is much increased. The fœtus is exposed to exceptional risk when obliged to pass through the entire stage of

dilatation of the os without the protection of the liquor amnii, for not only are its parts subjected to injurious pressure, but owing to the much greater degree to which the uterus can contract, the interruption to the supply of maternal blood to the placenta is much more complete. Yet it is possible for the fœtus to retain perfect vitality for many days after the escape of the liquor amnii, as is shown in the following cases:

Mrs. M., æt. 38, sent for me in June, 1878. I found her pregnant with her eighth child. She was in a state of great anxiety on account, as she asserted, of the escape of the waters, which she told me had come away in large quantities. Examination did not convince me of the accuracy of her statement, and I concluded she had mistaken the source of the aqueous flow. One thing was certain, however, and that was that she was not then in labor, although very near her time. She was enjoined to keep quiet, though rest in bed was not insisted upon. Five days afterward I was again sent for, and found her in the first stage of labor, but no membranes could be felt. She was safely delivered of a living child. If the membranes really did rupture at the time supposed, this is the longest period between the rupture of the membranes and the coming-on of labor I have met with personally; but the following cases represent the possibility of the preservation of the vitality of the fœtus under these unfavorable circumstances for a much longer period:

Dr. Matthews Duncan reports a case in the *Lancet* for June 29, 1872, in which forty-five days elapsed from the time of the rupture of the membranes to that of the birth of the child. During the whole of this period the liquor amnii continued to escape as it was secreted, and the size of the uterus, as felt through the abdominal walls, was greatly diminished. When labor took place a seven-months' fœtus was born, and lived for several hours, although much deformed by the protracted pressure to which it had been exposed.

In the *Medical Times and Gazette* for September 18, 1852, Dr. John Gould reports a case in which twins, a boy and girl, were born living five weeks after the waters had come away.

Although the above cases are well authenticated, especially that of Dr. Duncan, in which the most careful observations were made, yet the asserted escape of the liquor amnii must be always received with great caution. The sources of the aqueous flow which may be mistaken for the liquor amnii are numerous. The spontaneous escape of urine is not infrequently mistaken by the patient for that of the liquor amnii, while the flow of profuse secretions of Cowper's glands; the rupture of a cyst of the chorion; of another developed or undeveloped ovum; of a cyst lying between the chorion and the amnion, may prove the source of the supposed liquor amnii. That the membranes may again close after having been ruptured has been proven. This is not accomplished by a process of healing, as was at one time supposed, but by the sliding of the different layers of which the membranes are composed upon each other, by which a small opening may be effectually closed. After closure of the amniotic cavity in the manner described, the liquor amnii again collects, for this fluid is continually secreted, as first shown by Winkler and demonstrated in Matthews Duncan's case.

A source of error in diagnosis as to the origin of the flow is in rupture of the membranes at a point within the borders of the os and out of reach of the examining finger. Here vaginal examination shows the presence of the membranes closing the os and which become tense during the pains, while the opening becomes patulous and admits of the escape of the liquor amnii during the periods of relaxation. Notwithstanding the occasional occurrence of cases such as I have just given, the usual result of the escape of the waters, at whatever period of gestation it may occur, is to precipitate immediate labor; and this labor, as already shown, is unusually distressing to the mother, and at the same time subjects the fœtus to increased risks. We have seen that the peril to the fœtus is due solely to the persistence or the frequency and violence of the pains interrupting too frequently, too persistently or too completely the supply of maternal blood to the placenta. The abnormal pains are not alone due to the irritation of the mouth of the uterus by the direct contact of the fœtal parts with the uterus, but also to the mental condition of the woman. Most women view the occurrence of rupture of the membranes at the beginning of labor with anxiety and alarm; and such a state of the mind is very apt to be reflected injuriously upon the action of the uterine muscles. Hence, care is necessary in the conduct of such labors; first of all, to reassure the patient, then to enjoin rest as soon as the pains come on, and if they are at all disposed to assume an abnormal character, to keep the woman constantly in bed and give opiates to control the severity of the pains, to preserve

the proper rhythm of the contractions, and to favor dilatation of the os.

Before closing this paper I wish to refer to another though kindred subject. I allude to the obscure symptoms sometimes occasioned in parturient women by the presence of intercurrent acute disease. I have several times been deceived by symptoms due to the malarial poison becoming manifest during labor or in the lying-in period, which have in the one case closely simulated approaching exhaustion, and in the other acute local inflammation. Sometimes the manifestations of the presence of this poison consist of chills followed by fever, while in other cases there is more or less severe neuralgiac pain alone. When the previous history of the patient has been obtained, and such history shows the presence of the malarial poison, the diagnosis of the true nature of the symptoms is not difficult, but it is so when no evidence of previous symptom of intermittent fever is attainable. The following case is one of this character:

Mrs. C., æt. 22 years, was taken in labor with her first child early in the morning of June 8. As she had been referred to me for attendance in confinement by her regular medical attendant, I had no opportunity of obtaining a personal knowledge of her previous health. I learned, however, that in so far as she knew she had never suffered from malarial poisoning. She had, however, suffered very much from almost continuous nausea and frequent vomiting at the beginning and toward the close of her pregnancy. The labor continued throughout the day, and in the evening became quite severe. The vertex presented in the first position. As the os dilated but slowly, and the patient's sufferings were severe, I ordered her to take a full dose of morphia. An hour or two later her symptoms were not satisfactory; her pulse was beating at the rate of more than 100 per minute, her mouth showed a tendency to dryness, constant thirst existed, and the patient frequently vomited bilious matter. Although the uterine contractions were very painful and frequent, they were short, weak, and inefficient. When the patient had been over twenty hours in labor, as the os was pretty widely dilated, I decided, in view of the symptoms, to apply the forceps and establish the second stage of labor, believing the physical strength of the patient to be sufficient to safely accomplish the subsequent stages of delivery. She was accordingly etherized to complete unconsciousness, and the head of the child brought through the os and down upon the floor of the pelvis. The forceps was then withdrawn. As the effect of the ether passed off, good expulsive pains came on, and in due time a living child was born without accident. The mother did well for the first nine days after delivery, although the frequent pulse continued, with much coating of the tongue and some headache, but without any febrile symptoms whatever. On the tenth day, however, while still kept in bed, she was seized with pain in the left iliac region, which on the following day became violent and did not yield to the small quantity of opium (a remedy which she could not take without very disagreeable symptoms) which I induced her to take. This pain was not accompanied by fever, and I had no doubt was malarial in its origin. Acting upon this belief she was placed upon full doses of quinine, when not only did the pain speedily disappear, but with it the frequent pulse, the headache and the nausea. The patient had come to live in the house in which she was confined but a few months before confinement, and the first evidences of the presence of the malarial poisoning in her system were those which appeared during her labor and subsequent lying-in. The dryness of the tongue and much of the nausea appearing during labor, were probably due to the opium I had given her.

Dr. Parvin remarked that the subject of Dr. Richardson's paper was one of great practical importance, and his presentation of it had been very interesting. Coming to its ultimate analysis, a case of labor, tedious in either the first or in the second stage, shows a want of proper relation between power and resistance; the former for an unusually long time is unable to overcome the latter. Manifestly if this be so, we have naturally suggested to us two plans of treatment: either increase the power or lessen the resistance. These principles are plain, but the selection and the application often present serious difficulties. Severe suffering in the first stage of labor certainly should be relieved, for this suffering exhausts, and it does not follow that the power of a pain is to be measured by the intensity of suffering it produces, and therefore "painful" pains are an undoubted evil. As to the means for their relief when they are associated, as they usually are, with very slow dilatation, many would prefer chloral injected into the rectum to morphia internally or anæsthetic inhalation. In regard to the process of dilatation of the os, it is possible Dr. Richardson has attached too much importance to the bag of waters as a dilating means; that is the mere passive

process, but there is an active process, that by which the circular fibres of the uterus are, by the action of the longitudinal fibres, retracted over the bag of waters, or the presenting part, if the former be ruptured; it is not so much the descent of the presenting part which occurs, as it is the ascent of the expanded cervix; for in primiparæ, at least, the head is usually at the beginning of labor in the pelvic cavity, and it can go no farther until the dilated os has passed more or less completely above it. It may be that resistance being lessened by chloral, or by opium, the power is sufficient to overcome it; but if it be not, probably the continuous current of electricity will be the most efficient means to increase the uterine force. In this connection, I may refer to the statements of Boyer, in his recent elaborate monograph entitled *Morphologie der Gebärmutter.* In many cases of labor where delay occurs in the first stage, it is not the os uteri that is at fault; the obstacle is higher up, and according to Bayer, the anatomical condition of this "*Stricturirung*" is the deficient unfolding of the cervix. In such condition there may be a spastic ring-like stricture or a spastic partial stricture. The first form is especially liable to occur in a narrow pelvis. Bayer recommends warm fomentations, warm vaginal irrigations, a whole bath, eventually narcotics, especially opium by rectal injection; but he strongly insists upon the continuous current as the true natural method of treatment, on the one hand relieving cramp and on the other exciting labor-activity, thus removing the primary failure, the deficient unfolding of the cervix. One word as to the occurrence of malarial poisoning in the puerperal woman. I think it comparatively very rare. Certainly this is the conclusion which I must draw from my own experience in private and in hospital practice. In two terms of service at the Philadelphia Hospital, I have seen probably forty cases of puerperal septicæmia, and only one case of malarial fever. When one sees a febrile attack in a woman after labor, he is disposed to take the most favorable view of the case, and may attribute, at first at least, the disease to malaria when really it is caused by septicæmia, losing precious time, and may be led to give a favorable when a doubtful prognosis should be indicated.

Professor Jaggard, of Chicago, upon invitation from the chair, remarked that morphia hypodermically had been extensively tried in the first stage of labor at Vienna and Paris, and had been discarded, in the former city about six years ago, and in the latter more recently. It had been found to affect the fœtus unfavorably. One-fourth of a grain administered every four hours for some time would be attended with grave elements of prognosis. The possibility of a live fœtus remaining in the uterus forty-five days after the escape of the amniotic fluid, he considered more than doubtful. Cysts sometimes form between the amnion and chorion, and the bursting of one of these may give rise to the idea of the escape of the amniotic fluid. Hydrorrhea gravidarum, a condition dependent on a diseased condition of the decidua, is a more frequent phenomenon, and will explain many of the cases of supposed rupture of the amniotic sac.

Dr. W. T. Taylor remarked that the causes of delay in the first stage of labor were numerous. For the relaxation of rigid os, he would prefer hydrate of chloral twenty grains. One-eighth of a grain of sulphate of morphia, every two hours has a soothing and beneficial effect, giving rest and sleep between the pains. When the edge of the cervix is thin and wiry, the morphia is especially called for. He has experienced delay from dropsy of the amnion. After a delay of six or eight hours, he has ruptured the membranes, and after the escape of an enormous quantity of fluid, rapid and effectual contractions supervened. Another cause of delay is posterior positions of the occiput; if a change of position can be effected, labor will progress more rapidly. He has observed premature escape of the liquor amnii from ten days to two weeks before labor, and yet everything went on normally. He has met with malarial poisoning in one case. In the eighth month intense pains were experienced, but there was no effect on the os. He gave five grains of quinine and ten grains of potassium bromide, and in a few hours the pain was relieved.

Dr. Longaker stated that according to his experience morphia should be used guardedly. In some cases it has caused still-births. In a recent case the first stage of labor had lasted twenty-four hours, and the os was but one inch in diameter; four doses of sulphate of morphine, one-fourth of a grain each, were, by mistake of the nurse, given at intervals of fifteen minutes; dilatation and descent of the child quickly followed. As Dr. Parvin has stated, the early stage of labor consists mainly of retraction of the cervix, and early rupture of the membranes as a trouble is overrated. Undeveloped pelves of generally small diameters cause less delay in first labors than in later ones, because in the earlier labors the abdominal muscles are strong to

assist the uterine contractions; in later labors, besides having less contractile powers, their laxity allows the body of the child to fall forward, and the vertex presents less favorably at the superior strait.

An Unusual Cause of Dystocia, Necessitating Embryotomy.

Dr. F. A. Seymour thus writes in the *Pacific M. and S. Jour.*, February:

Mrs. A., primipara, was seized with labor at term, on the afternoon of December 30, 1884. Her attendant, Dr. F. T. Bicknell, was summoned at 8 p. m., at which time uterine contractions of average normal vigor and duration recurred at intervals of five minutes.

Digital exploration revealed a healthy and natural condition of the soft parts. Dilatation of the external os was well advanced, and through the membranes a vertex presentation was easily discernible. At 10 p. m., spontaneous rupture of the amniotic membranes occurred. Complete dilatation followed, and the vertex engaged in the superior strait. The pains proving persistent and exhausting, several five-grain doses of chloral hydrate were given by mouth at half-hour intervals, but without effect. At 2:30 a. m., morphinæ sulph. gr. ¼ was administered, and from three o'clock a. m. until six the patient slept. Soon after awaking, the pains resumed their frequency and force, but examination detected no fœtal advance.

There seemed to be absolutely no obstruction; the pelvic space was ample, and the presenting head not unusually large. At 7 a. m., Dr. B. applied the forceps, making gentle traction and rotation, purposing thereby to stimulate an apparently misdirected *vis a tergo* to an expenditure of energy in the proper pelvic axis. But the attempt proved unavailing. As the morning wore away there was no change in the character of the uterine pains, nor in the fœtal position. About 10 o'clock a. m. the patient's circulation showed signs of involvement, the pulse becoming rapid and compressible. Dr. Bicknell then requested counsel, and a messenger was sent for the writer. On examination, the condition proved as above described. The liquor amnii had evidently wholly escaped. The uterine walls were firmly contracted upon their contents, and the cervical lips retracted over the head and beyond the reach of the exploring fingers. There was no apparent reason why the case should not progress without interference; and further delay would probably have been advised, except for the persistence and increase of the circulatory disturbance. The possibility of version was excluded. Ether was administered, and I applied the forceps without any difficulty. But the fœtus could not be moved. Repeated efforts proved wholly futile. On further consultation, embryotomy was determined upon. After evacuating the contents of the cranium and crushing in its walls, extraction was effected only after tedious delay and the repeated application of great force.

Singularly enough, after the slightest advance had been secured in the direction of extrusion, but little additional force was requisite to complete the delivery. The sensation imparted to the manipulating hand was similar to that of slipping suddenly past an obstacle. The fœtus weighed but eight pounds, and the pelvic conjugates were normal; hence the source of resistance was enigmatical, until, on introducing my hand into the uterine cavity to effect the removal of the placenta, the cause was discovered.

On the right side of the uterus, at a line about midway between the external os and the fundus, the entire thickness of the powerful muscular wall projected inward with great firmness, constituting a shelf or semicircular ridge. This had evidently grasped the fœtus, the knees resting above it, and thus delivery had been impeded. In a careful study of this unique experience, light has been thrown upon very many cases in my note-book, of dystocia associated with premature rupture of the membranes, and for which, until now, I have found no satisfactory explanation.

"A dry labor is sure to be tedious," is a popular aphorism so frequently true, that it practically passes current with the profession as well. The tedium of these cases has hith-

erto been associated chiefly with (1) the removal of the protruding membranes as a distending agent, both for the uterine orifice and the vaginal passage; and (2) with the impossibility, except in rare instances, of the presenting part making pressure directly upon the os itself. But every practitioner of large experience may readily recall numerous instances in which, despite the premature escape of liquor amnii, cervical dilatation progressed with normal rapidity, while the pelvic soft parts, moist, flexible and roomy, awaited for hours the slow fœtal descent.

Darwin's Doctrine of Evolution in Explanation of the Coming into Being of Some Diseases.

Dr. Aitken thus concludes a series of articles in the *Glasgow Med. Jour.*, February, 1886:

Thus Darwin's great work comes to be in accordance with the teachings of physiology and pathology in this respect, that "disease is not inevitably the fate and birthright of every born child, but that much of it is, in fact, of our own making; that it is not outside our knowledge and our power, but that much of it is within our own control; that filthy conditions and the imperfect removal of effete material without and within the body are the most powerful concurrent factors alike of constitutional ailments and of the zymotic pestilences which aforetimes 'walked in darkness,' but which are daily being made plain by the revealing light of science."

"Slowly, but surely, evolution brings about an increasing amount of happiness; all evils being but accidental. By its essential nature the process must everywhere produce greater fitness to the conditions of existence, be they what they may. There is in all cases a progressive adaptation, and a survival of the most adapted, and the evils accompanying evolution are self-eliminated."*

Hence there is in Darwin's doctrine of evolution throughout all nature the comforting belief that "it implies the design of a perpetual progress." But his too enthusiastic followers have attempted to carry his hypothesis farther than he did himself. They have endeavored to push the doctrine of evolution so far as to make it account even for the origin of life itself—a problem which Darwin never attempted to solve; but this much is certain, that "all evidence, up to the present, negatives the opinion that 'LIFE' is a mere evolution from organic matter;" and while the origin of diseases *in the beginning*, like *the first origin of life on the earth*, as well as the continued life of each individual, is unaccounted for by science, and quite beyond its scope, the doctrine of evolution demands (as Darwin himself assumed), 'that we should look on the Almighty as creating the original elements of matter; determining their number and their properties; creating the law of gravitation, whereby, as seems probable, the worlds have been shaped; creating the various laws of chemical and physical action by which inorganic substances have been combined; creating, above all things, the *law of life*, that mysterious principle which plainly contains within itself such wonderful possibilities, and thus providing *once, and for all time*, the ultimate development of the many forms of nature by which we are surrounded."

Surely, "we can conceive nothing grander than this one original creative act from which the infinite variety of the universe has come, and more is coming yet."

And this doctrine of evolution further teaches us, "that we are looking on a work which is not yet finished; that we are looking on a world in which the occurrence of pain, of disease, of death, and such like imperfections, are but a necessary part of this large design, the general outlines of which, thus far, we have been permitted to see, but the ultimate issue of which, with all its details, is still far beyond our perception."

*Herbert Spencer, Principles of Biology, vol. i., p. 354.

Remarkable Toleration of a Foreign Body by the Eye.

Dr. Bruns thus writes in the New Orleans *Med. and Surg. Jour.* for February:

Joseph Messina applied for relief September 28th, 1885.

Born in Italy, he is twenty-nine years old, a resident of the State for three years, and at present a laborer in the rice fields of St. James Parish.

Patient states that a year ago he got a piece of rice husk in his left eye. For a day or so it caused him some annoyance. This passed away, and he has not thought of it until very lately. Very recently the eye has been troublesome; it is irritable and waters a little when he is exposed to the sun or wind.

There is a very slight circumcorneal injection, more marked around the lower portion of the cornea. Upon the latter, downwards and outwards near the inferior limbus, a small, round, yellowish brown spot about one-eighth of an inch in diameter is seen. Close inspection convinces Dr. Bruns that this is the offending bit of rice husk.

The eye being thoroughly cocanized, the husk is found to be very closely applied to the surface of the cornea, and covered with quite a thick layer of somewhat inspissated secretion (mucus), but is removed without pain or difficulty, and the patient sent on his way rejoicing.

The great degree of toleration manifested by the cornea towards the foreign body in this case, was due to the smoothness and thinness of the latter, allowing it to be closely and evenly applied to the corneal surface.

It is said that in the great grain-growing regions of the West, bits of husk often get into the laborers' eyes and set up severe conjunctival inflammations, which often resist regular treatment with approved collyria.

The quacks of the country, with that superior keenness which is unhappily so often the associate of knavery, have penetrated to the cause of these cases, and often bring relief where the regular practitioner has failed. They search the eye thoroughly, especially the upper conjunctival *cul de sac*, quietly remove the foreign body, and giving their patient a little rose-water, have him well in a day. The moral is obvious.

Poisoning by Chlorate of Potassium.

Dr. Simmons B. Jones, of Charlotte, N. C., reports the following interesting case in the *Med. Record:*

A little girl, nine years of age, had been under his care for a slight fever, with weak pulse, nausea, and continual vomiting, but, having apparently recovered, was dismissed as cured. On the day following, July 26th, the child had a sore mouth, and her mother gave her a paper containing something over an ounce of chlorate of potassium, allowing her to take it *ad libitum*. The girl liked the taste, and ate the crystals all day, consuming in this way between two and three hundred grains. At about two o'clock on the morning of the 27th the patient awoke vomiting. When seen some five hours later she was deathly pale, with blue lips, and a very rapid and feeble pulse, and presented exactly the appearance of one who had had a sudden and copious hemorrhage. "I had no idea at this time of the cause of the trouble, the parents having said nothing about the chlorate of potassium, believing it to be a harmless drug; but I suspected poisoning. The patient remained in this condition the three following days, vomiting and being unable to retain any food, and passing no urine. On the fourth day I introduced a catheter and drew off about five ounces of smoky urine, which, on examination, was found to contain albumen, casts, and altered blood. Dr. H. Formad, of the University of Pennsylvania, who examined a specimen, reported: 'I fully coincide with you about the urine; it contains a very large quantity of granular blood, epithelial casts, and free blood, showing a profound renal affection.' The urine was drawn for several days, and then began to be passed naturally in sufficient quantity, the blood disappeared, and the water resumed its normal color. An analysis, by Dr. Hannah, of eight ounces drawn the second day, showed six grains of potassium chlorate. The vomiting continued until August 14th, the matter vomited consisting of dark green mucus of an offensive odor. On August 16th there was seen an eruption of small maculæ of a purple color, upon the forearm. The temperature rose to 100° on the 20th, the submaxillary glands became swollen, the throat was red and œdematous; the patient sank gradually, and died on August 26th. She never complained of much pain, and there was no tenderness over the stomach. The bowels were at first constipated, but when action was solicited the matter passed was dark, and resembled the urine in appearance. There was complete anorexia throughout the entire period. Life was sustained by enemata of beef peptonoids, and milk, until the rectum became too irritable to retain the injections. After the vomiting had ceased, the patient was able to retain a little buttermilk. During the first few days much relief was obtained by warm baths, which were always followed by profuse perspiration and quiet sleep." No autopsy could be obtained.

Habitual Abortion and Kidney Disease.

The *Brit. Med. Jour.* says much has recently been written on albuminuria in pregnancy, and on the relation of disease of the kidney to physiological and morbid enlargement of the uterus. At the recent meeting of German scientists and medical men at Strassburg, Dr. Fehling, of Stuttgart, read a memoir on habitual death of the embryo in kidney disease. In the first case under his observation, premature expulsion of a dead fœtus occurred six times, and there was no evidence of syphilis. At every pregnancy, anasarca, albuminuria, and death of the fœtus, with severe cramp of the abdominal muscles, occurred between the fifth and sixth month; the dead fœtus was expelled from three to ten weeks later. In the second case, similar symptoms appeared in a young

unipara; the fœtus died, and thereupon the albuminuria abated. In the third case, the patient had borne two healthy children. During the third pregnancy, albuminuria and characteristic changes in the retina occurred; and during the fourth she was seized with hemiplegia; in both, a decomposed fœtus was expelled at the fifth month, with subsequent decrease of the albuminuria. In the fourth case, the patient, in her first pregnancy, aborted at the fifth month; then she gave birth at term to a recently dead child. In the third pregnancy, great œdema and albuminuria supervened, the child was still-born, and the mother died of uræmia. Dr. Fehling believed that, in all these cases, kidney disease existed before pregnancy, which aggravated the renal symptoms. Winter had described two cases of premature detachment of the placenta, normally situated, where albuminuria existed. Dr. Fehling found atrophy of the villi of the chorion, with wedge-shaped or spherical infarcts in the placenta, in his cases, similar to renal infarcts. The infiltration of the chorionic villi and vessels of the umbilical cord with small cells, as seen in syphilis, was absent, nor did any of the embryos exhibit a trace of congenital syphilis.

The Control of Hemorrhage.

Dr. A. Maguire thus writes in the *New Orleans M. and S. Jour.* for February:

In ante-bellum days, I was called to a large plantation in my neighborhood by the manager, one of the old-time overseers, who had great confidence in his powers of healing, and was convinced of his superiority over any new-fledged Æsculapius, and that what he did not know of medicine was not worth knowing.

He pointed to a collapsed, ghastly-looking African, sitting on a verandah, with his head leaning against the brick pillar, blanched as much as his color allowed, and with a small stream of blood and saliva trickling from one corner of his mouth; he had extracted, twenty-four hours before, the third molar, and the blood had never stopped—he had applied strong vinegar, Pravaz's perchloride of iron, nitrate of silver, and had caused the blacksmith of the plantation to bend and file down to a point a goodly-sized wire with which he had cauterized the socket. After doing all this he confessed he was at his wit's end, "*au bout de son latin.*" I told him I would extend his Latin to "*Felix qui potuit rerum cognoscere causas,*" and after reviving the drooping African with a square dose of whisky, I made a wad of cotton to be compressed between his jaws, leaving a piece protruding in the mouth of sufficient size to allow the involuntary play and suction of the tongue to be exerted on it, and not disturb the formation of the clot in the socket. The hemorrhage was arrested in ten minutes.

Some time afterward, a planter living some ten miles from my house sent for me for his daughter, who had been bleeding some twelve hours from same cause. I directed the father to apply same wad, and gave two doses of brandy and digitalis, which set everything right.

On the same principle, violent epistaxis can be controlled in many instances by occluding the nostrils between thumb and finger, preventing the forced entrance in and out of air, also an involuntary act, during which no clot can be formed.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——*Godey's Lady's Book* for March presents some notable attractions, not the least of which is a cleverly executed frontispiece portraying "The Frown," a companion picture to "The Smile," which proved to be such a point of merit in the January issue.

——A catalogue and price-list of artifical anatomical models can be had by addressing Dr. Lemercier, No. 7 Rue Vavin, Paris.

——At the last meeting of the Philadelphia Social Science Association Dr. Benjamin Lee read a paper on the organization of local boards of health in Pennsylvania, copies of which can be had by addressing the Social Science Association, 720 Locust street, Philadelphia.

——In a reprint before us, Dr. P. T. Armstrong, of the Marine Hospital Service, describes an interesting case of necrosis of the frontal bone following inflammation of the frontal sinus.

BOOK NOTICES.

Lecons sur l'Etiologie et la Prophylaxie de la Fiévre Jaune. Par le Dr. Manuel Cremona y Valle. 8vo., pp. 299. Illustrated. Mexico, 1885.

The scourge of tropical America is the yellow fever, and that its destructive ravages

are not limited to the tropics has been fearfully illustrated by the medical history of our own country. Any discovery which would offer a reasonably sure and easy method of prophylaxis against it would be one of the greatest boons to humanity, and would open up to the access of immigrants vast tracts of fertile land now effectually closed to them.

There seems good reason to believe that this discovery has been made by Dr. Carmona y Valle, the author of the work before us. It is by the method of inoculation of the specific virus of the disease into healthy subjects. Very strong testimony to the same effect has also been laid before the scientific world by Dr. Freire, of Brazil, who indeed claims to be the author of the method. Into the question of priority we shall not enter, and it is quite possible that like many discoveries it was originated independently by more than one observer.

Dr. Carmona's volume is published in French by the Mexican Ministry of Public Works, with an introduction and notes by Dr. E. Liceaga. It is illustrated by photographs and chromo-lithographs representing the specific microbe to which the disease is attributed. The explanation of the symptoms is ingenious, and the origin of the disease in various localities is carefully studied. The method of inoculation is described, and its protective effects demonstrated by the record of numerous instances of exposure without contracting the disease. Altogether the book is one of the first order of importance in prophylactic science.

On the Supra-pubic Operation of Opening the Bladder for the Stone and for Tumors. By Sir Henry Thompson, F. R. C. S. Pp. 57. London: J. & A. Churchill, 1886.

This interesting monograph contains a history of the operation, a record of a number of cases, and a discussion of its merits as compared with others for the same purpose. It is well illustrated, and written with the usual ability of the author.

Practical Human Anatomy. By Fanueil D. Weisse, M. D., etc. Illustrated by 222 lettered plates, containing 321 figures. 8vo., pp. 456. William Wood & Co., New York. 1886.

This treatise is intended both to be a working guide or dissector for the use of students, and also a reference book on anatomy for practitioners. The illustrations are on stone and are generally satisfactory, though here and there the lettering is less clear than one might desire. Their great merit is that they are nearly all directly from nature by the hands of a most competent artist, and not borrowed from previous treatises.

The text is concise and clear, and confines itself strictly to the anatomy of the part, not embracing its surgical aspects. To many this will doubtless be a disappointment, but we agree with the author in his opinion that anatomy is a science by itself, and should at first, at all events, be studied as such. After the description of each organ or part, the rules for its proper dissection are given in print of a smaller size. As the author has had experience in teaching anatomy in one of the largest medical colleges in New York for many years, he has acquired a thorough knowledge of how best to present his topics so as to insure their facile comprehension. The work is provided with extensive indices, and is manufactured in a highly satisfactory manner.

The Temperance Teachings of Science. By A. B. Palmer, M. D., LL. D., etc. Pp. 168. Boston: D. C. Heath & Co., 1886.

This is one of the books "adapted to the use of teachers and pupils in the public schools" which have been brought into existence by the educational tactics of the total abstinence crusaders, to which we referred in a recent issue. It comes from the pen of a member of our profession justly distinguished for his learning, and not less for the aggressiveness with which he defends his views.

In his book, as in others of the kind, the real point is dodged. Dr. Palmer labors to prove what no one denies—the evils of intemperance—and then by these pretends to have shown that temperance—the moderate use of fermented beverages—is also hurtful. A more complete ignorance or disregard of logical method could not be adduced. It is equalled by the physiological absurdity which prevails throughout the work, of maintaining that the effects of fermented are the same as those of distilled liquors. It is paralleled by the author's complete misapprehension of the evils of total abstinence, shown in his remarks on page 162. He fails to grasp this, which is one of the most important points in the whole subject. No nation and no party will ultimately succeed which departs from the doctrine of Him who came "eating flesh and drinking wine," who was Himself straightly charged with being "a wine-bibber and a glutton," but who in all matters of food and drink taught "temperance in all things, abstinence from nothing." To this all sound physiology points, and all education and government should point.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE MANUFACTURE OF ACETATE OF LEAD AND ITS INJURIOUS INFLUENCES UPON THE WORKINGMEN CONNECTED WITH IT.

For years science has endeavored to prevent lead-poisoning in those whose occupation brings them into intimate and continuous contact with the metal.

Not only in the foundry-department, but still more in those, where the product is powdered, collected and packed ready for shipment, poisoning by lead is possible. Dr. F. Boehm has made many observations in this respect, and from his article in the *Deutsche Med. Zeit.*, Jan. 11, 1886, we make the following extracts:

It is of importance to know, that the first symptoms of intoxication consist in disturbances of digestion, and if the laborer does not then consult a physician, signs of lead colic develop, soon followed by vomiting, cold perspiration and intense colicky pains, with violent constipation. Under correct treatment, improvement sets in within a few days. Should the laborer return to the factory after repeated attacks of lead colic, chronic poisoning occurs; lead tremor, paralysis of the extensor muscles, epileptiform convulsions and affections of the joints belonging to its symptoms. In some cases peculiar physical disturbances occur; the patient is seized with mania, or becomes an idiot. These signs of mental aberration generally last some weeks, and then cease, only to return after intervals varying from one to several months, if the patient, notwithstanding his physician's advice to the contrary, should again resume his former occupation. Females are far more predisposed to lead-poisoning than men; this is the reason why in the great lead factory in Gademann in Germany female help is no longer engaged. It has been demonstrated that men in the habit of chewing tobacco generally escape lead-poisoning or are far less predisposed to it, but science has not yet divined whether this fact is due to any special action of the nicotin, or whether in consequence of the greatly increased salivary secretion in chewers, the small particles of lead are expectorated or made more or less innocuous by the alkalinity of the saliva. If at the very commencement, when only disturbances of digestion and an inclination to constipation exist, laxatives are promptly administered, the outbreak of the lead colic may be prevented. But should any pain exist, laxatives are not only without effect, but directly injurious. Warm cataplasms, opium internally or morphia subcutaneously and only after cessation of all pains the administra-

tion of drastic purgatives, form then the correct treatment.

As prophylactic measures, the following are in vogue in the large factory mentioned, which, by the way, is looked upon as the model institution of its kind. Laborers receive special *overalls*, which they wear while at work, and peculiar gloves, so arranged as tightly to surround the wrist without interfering in its motion, thus preventing all absorption by the skin, as the overall and gloves are of a material which is impermeable for the finest dust. Immediately before meals—which are permitted to be taken only in certain rooms and at definite hours—and also after their day's work is done, the overalls and gloves are carefully removed; face, hands, and hair are thoroughly washed; the teeth are cleansed with special brushes, and pure water is inhaled through the nostrils; in the rooms where the lead is worked as powder every laborer is forced to wear a respirator—incorrect wearing of which, if detected, at once causing the discharge of the man—and at least twice daily every laborer must take a tepid bath.

Experience, however, has proved that the men are too indifferent to prevent the occurrence of lead-poisoning. While those who strictly follow the rules, as mentioned, and who use all the year round, instead of plain water, a lemonade made with diluted sulphuric acid, may work for years and years in such factories with perfect impunity, others become poisoned by lead because they neglect the necessary precautions. Only technical chemistry, by the invention of less injurious coloring material, can cause the disappearance of the frequently dreadful disease.

LIVING IN NEWLY BUILT HOUSES.

In Prussia exists a law forbidding the renting of newly built houses for a stated period after their completion. This period somewhat varies according to the amount of humidity in the soil of the district. Recently a commission was appointed to investigate the subject, and to determine whether any change in the law would be desirable, the law having been in existence for over thirty years.

This commission has recommended the abolition of the law, and the substitution instead of more stringent building regulations. They say that the government should insist in any new building upon all measures necessary to prevent entrance of water into any part of the house. In regions where the ground water often rises high, a layer of cement should hermetically surround the cellar and ascend to a certain height above ground. Other precautions are recommended for the purpose of insuring water-proof roofs. But the main point in the commission's report is the question of ventilation. They advise the government to appoint a commission to determine the most feasible plan for insuring perfect ventilation in all dwellings and, then to pass laws enforcing such ventilation in all newly built houses.

In conclusion they express the positive conviction, if their recommendations are carried out, and if the respective building authorities see that no defect in ventilation, or in the other measures, can creep in, that newly built houses can at once be tenanted as soon as they are completed, without the least injury to the health of their occupants.

There is no doubt that a similar stringent law and its stringent enforcement by competent building commissions are just the things needed in our country. But if we remember that, in a city like New York, a tenement house before its completion can cave in, simply in consequence of a little breeze, as happened about a year ago, when only the accidental fact of a person being killed by the collapsing walls insured the punishment of the builder (but not of the commissioners!) it surely is time to enact some such laws this side of the Atlantic, and to take as commissioners men that not only understand their business, but are determined to carry out the provisions of the law.

SULPHUR IN GAS.

The question has recently been agitated, whether our illuminating gas contains any considerable amount of sulphur, the idea having gained ground that this substance, if present, would be injurious to the health of persons inhaling air saturated with it. The well-known authority on sanitary matters, Von Pettenkofer, has made this subject a special study, and after a long series of experiments he has came to the following conclusions, published in the *Deutsche Med. Zeit.*, January 11, 1886:

He is of the positive opinion that it is of no importance whatever, from a sanitary point of view, as well as from a chemical-technical one, whether an illuminating gas, *provided it be free from sulphuretted hydrogen*, contain 0.2, or 0.5, or 0.7 (about $\frac{3}{10}$ grains) sulphur per cubic meter, or none. Those using the gas have not to expect any advantage whatever from the present chase after sul-

phur in gas; it can be of interest to them only that the gas is free from sulphuretted hydrogen, and that it possesses sufficient illuminating power.

Thus one other of the recent scares has been removed from anxious brains. There is no doubt that many of our modern achievements, as for instance gas, aqueducts, sewerage, etc., are by no means conducive to health; but in the chase after injurious influences, and after factors deleterious to health, many a wrong position has been maintained, and this will probably continue until science has finally sifted the material accumulated, and determined what is hurtful and what not.

Notes and Comments.

The Surgical Treatment of Cysts of the Pancreas.

Of all abdominal organs the pancreas has been least frequently subjected to surgical treatment, for which the anatomical location of this organ, and the obscurity of its affections, furnish a sufficiently satisfactory explanation. Situated high up in the abdominal cavity, and hidden behind such important organs as the stomach, omentum, and transverse colon, it is the least accessible of all abdominal organs, and on this account its affections, wrapped in obscurity, have for the most part constituted objects for empirical medication. The relation of this gland to the surrounding organs and its great distance from the anterior wall of the abdomen, the only point of approach, necessarily offer serious obstacles to diagnosis and direct treatment. From a diagnostic point of view another great difficulty is our want of positive knowledge concerning the physiological functions performed by this gland in the process of digestion. As the symptomatology of all affections of the pancreas is always obscure, and a probable diagnosis can only be made in cases where the gland has become considerably enlarged by disease, it is apparent that our present clinical knowledge is limited to diseases which increase the size of the organ to a sufficient extent to permit its detection by palpation. Primary malignant disease of the pancreas, when it has advanced to such an extent that its presence can be diagnosticated with certainty by physical signs, will have invaded the adjacent tissues to such a degree as to preclude the advisability of an operation; consequently the efforts by the surgeon, for the present at least, must be directed exclusively toward the recognition and treatment of benign affections of this gland. Clinical experience does not extend beyond an imperfect knowledge of cysts of the pancreas.

The pancreas, like other secretory organs, is prone to become the seat of cystic tumors, the result of obliteration or obstruction of the common duct, or one or more of its branches. Cysts originating in this manner are true retention cysts, containing the physiological secretion from the distal portion of the gland tissue, with perhaps accidental products, such as altered secretions, blood, and the products of inflammation.

In a very valuable paper on the surgical treatment of cysts of the pancreas, Dr. N. Senn, of Milwaukee, in the July number of *The American Journal of the Medical Sciences*, presents a full report of a case of retention cyst of the pancreas, which has recently come under his observation, and, at the same time, summarizes, in a compact form, the clinical history of similar recorded cases which serve as a basis for some general remarks.

In recapitulation, Dr. Senn submits the following conclusions:

1. Cysts of the pancreas are true retention cysts.

2. Cicatricial contraction or obliteration of the common duct or its branches, and impacted calculi, are the most frequent causes of cysts of the pancreas.

3. A positive diagnosis of a cyst of the pancreas is impossible; a probable diagnosis between it and some other kind of cysts amenable to the same surgical treatment is adequate for all practical purposes.

4. The formation of a pancreatic fistula under antiseptic precautions recommends itself as the safest and most expedient operation in the treatment of cysts of the pancreas.

The Influence of Cocaine, Atropine, and Caffeine on the Heart and Blood-Vessels.

There are few known drugs that have, within such a short space of time, risen from comparative obscurity to such practical as well as theoretical importance as cocaine. Its great value as a local anæsthetic, and its wide application in all the branches of medicine and surgery, together with our comparative ignorance in regard to many points of its action on the animal organism, are sufficient to attract attention to a valuable experimental paper on the influence of cocaine, atropine, and caffeine on the heart and blood-vessels, by Dr. H. G. Beyer, U. S. N., which

appears in the July number of *The American Journal of the Medical Sciences.*

Dr. Beyer finds—

1. That *cocaine* is exceedingly prompt and uniform in its effects upon the heart.

2. In small doses it is a powerful stimulant to the heart's action.

3. In medium doses it has an inhibitory influence over the ventricular contractions.

4. In large doses it produces diastolic arrest, from which, however, the heart may be recovered under suitable conditions.

5. In small or large doses it produces contraction of the blood-vessels, independent of the central nervous system.

6. A rise in the blood pressure, consequent upon the administration of cocaine, is due to a direct action of the drug on the heart and blood-vessels, stimulating the former and constricting the latter; a fall in blood-pressure coming on after the rise must be accounted for by the action of cocaine on the heart alone, since its constricting influence on the blood-vessels outlasts the stimulating influence it exerts over the ventricle of the heart.

2. That *atropine* in certain doses increases the rate of beat of the heart, and also the amount of work done.

2. That it exercises an inhibitory influence over the contractions of the ventricle.

3. That it first causes a contraction and afterwards a dilatation of the blood-vessels.

4. That cocaine acts on atropized vessels in the same way that it does on normal ones, *e. g.*, it causes their contraction.

That *caffeine* in small as well as large doses produces dilatation of the blood-vessels in the terrapin; any rise in arterial pressure due to caffeine is, consequently, to be explained only by the stimulating effect caffeine exerts on the heart itself.

A New Symptom in Megrim and Epilepsy.

Before the Clinical Society of London (January 22), Dr. Angel Money read a paper with this title. The patient in whom the new symptom was noted was a man, æt. 29. He had suffered from many of the symptoms that are usually put down under the heading of megrim, such as transient hemiopia, spots and flashes of light, headache with and without nausea, abnormal tactile sensations. When about eleven years old he used to faint with a queer sensation at his epigastrium. The new symptom consisted in an apparent momentary lengthening of a written or printed word, seemingly caused by a reduplication of one or more of the letters in the word. The patient observed that this annoying symptom was most frequent when the flashes of light were most troublesome. Another noteworthy fact in connection with his visual organs was the long persistence of negative images, a condition which was not always present, but only at the times when he felt bilious. There had never been convulsions or motor spasms of any kind; nor with the exception above mentioned has he ever lost consciousness. At times the patient was troubled with a ringing noise apparently in his right ear; he was, however, distinctly though not very deaf on the right side. Reflecting on this symptom of apparent lengthening of a word, it occurred to Dr. Angel Money to ask his patient whether he ever experienced a similar alteration in the length of spoken words. There was no weakness of any ocular muscle, and only a trifling degree of myopia. The author remarked that there were many ways of interpreting this symptom. He did not think there was any fraud or reasonable doubt that the symptom was a real one. Was it due to some transient disturbance in the muscular mechanism of the eyes? The author thought this supposition not at all improbable. But he considered that theoretically it must not be overlooked that we may have to do with a symptom belonging to what may turn out to be an altogether new field of sensory nervous symptoms, by which he meant a group of symptoms which might best be designated as "reduplicated nervous actions." If the patient be right in his opinion that one of the letters of a word is doubled in the apparent lengthening, then it would not be at all absurd to regard the phenomenon as due to the reduplication of a nervous discharge in the usual word centre.

Chronic Simple Ulcers of Stomach and Duodenum without Symptoms until the Occurrence of Perforation.

The following case, which Dr. Samuel West reports in the *Med. Press*, January 27th, is well worthy of remembrance, as it serves to help us out of "scrapes:"

Hannah A., 48, while eating, was seized with sudden severe pain in the epigastrium, which continued until her admission a month later. She had vomited, but food produced neither pain nor sickness. She had rapidly lost flesh and strength, and had recently perspired at night, and for a few days had a cough which caused her pain in the right side and back. She had been all the

time confined to bed, and a bed-sore formed upon the right buttock a fortnight before admission. Though she had been losing strength lately, there was no history of any ailment before the present illness. There had never been any pain or discomfort after food. Patient looked very ill. Respiration 46, shallow, general rhonchus. P. 120, very fresh. T. 99°. Urine a trace of albumen. Liver uniformly enlarged. Some tenderness above umbilicus and towards right hypochondrium. No ascites, but œdema of legs. Two days after admission she passed with a stool about six ounces of dark blood, and also on the two following days. She rapidly became weaker, and died on the 5th day after admission. P. M.—Some old chronic pleurisy and pericarditis. Liver enlarged, with superficial abscess between it and abdominal walls. This abscess had two openings—one leading from duodenum and due to perforation of an old ulcer, the second into the colon, probably accounting for the hæmorrhage. Another large chronic ulcer was found upon the lesser curvature of the stomach, which had also perforated, and led into a cavity with thick fibroid walls, and the base of which was formed by the liver. The two ulcers were of very old date, the symptoms being produced by the perforation of the duodenal ulcer, and the formation of the abscess. Two points are noteworthy:—1. The extent and duration of the ulcers without symptoms. 2. The lowness of the temperature in spite of active suppuration.

Weighted Shoes in Locomotor Ataxia.

Dr. Allan McLane Hamilton thus writes in the *Boston M. and S. Jour.*, January 21:

Those of us who are in the habit of seeing locomotor ataxia, especially in its second and third stages, have our sympathies taxed to their utmost by the helplessness of the tabetic patient and his difficulty of getting about. There is very little to be done at best, and for this reason the case seems sadder than ever.

For such ataxics I have been in the habit during the past four or five years, of suggesting a simple mechanical device which has done so much good that I think it worthy of publication. I allude to weighting the anterior part of the feet. Many ataxics whose locomotion was exceedingly difficult and distressing, have worn their weighted shoes constantly since I ordered them, and have led far happier and more comfortable lives.

Those at all familiar with the peculiar heel gait of the ataxic, know that there is more or less weakness of the peroneus longus, and a failure to act against its opponent, the tibialis anticus, which is strongly contracted. Buzzard and Jackson first called attention to this explanation of the disorderly walk which largely depends upon what the former calls the "over-movement of the associated muscles." The use of the properly adjusted toe-weights serves two purposes—*first*, to overcome the tendency to violent hyperflexion; *secondly*, to create an exaggeration of subjective consciousness of movement and location. The loss of plantar tactile sensibility is compensated by the perception of weight. In some cases with the adjusted weight it is possible for the patient to walk in the dark, which under other circumstances he could not do.

The weight, which should not be so great as to produce fatigue, may consist of a leaden insole, or of a plate fastened between the soles. A few experimental trials will enable the physician to determine just how much lead is needed, and where it should be placed. For those cases which last some time, the degree of comfort is sometimes very great, and the patient's gait is less apt to attract the attention it would otherwise, thus saving him much mortification and giving him greater confidence.

The Prevention of Myopia in School Children.

It is now tolerably well established that shortsightedness is developed and increased in a certain direct relation to the amount of school-work done by children. For the prevention of myopia, Fuchs, of Liège, in a prize essay quoted in the *Birmingham Medical Review*, gives the following directions. First in importance is the arrangement and lighting of the school-room.

"The principal windows in England should look to the south or south-east. The long axis of the room should run north and south. Every scholar should, from his place, be able to see some portion of the sky. Light from above is the best, and, except in hot climates, glass roofs are very advantageous. The chief light must come from the scholar's left side. The height of the top of the window from the floor should not be less than two-thirds the width of the room. The total window surface should bear to the area of the floor a proportion of at least 1 to 5. In artificial lighting by gas, every burner must have a glass chimney and a shade, the latter arranged to reflect the light down upon the desk, and to screen the scholar's eyes. There

should be about one burner to every four scholars."

Azoturia.

The *Lancet* (January 2) says that an estimation of urea discharged in a given time has been long regarded as a scientific means of diagnosis, not only in renal disease, but in other disorders which disturb the normal exchange of material. Within the last two or three years M. Rommelaere has made certain statements which, if true, would certainly afford additional help in the differential diagnosis of gastric diseases. Azoturia is a convenient term to signify the normal discharge of nitrogen in urine. It used to mean hyper-azoturia, and we now also speak of hypo-azoturia. But difficulties still exist in the way of nomenclature, for no one knows the normal discharge of nitrogen. It is asserted in text-books of physiology that 500 grains of urea are the normal amount discharged by the average healthy man in the twenty-four hours. But this seems to be an arbitrary standard. The objections that have been raised against Rommelaere's conclusions (*vide The Lancet*, p. 604, vol. ii., 1884) are four in number: 1. The estimate of thirty-two grammes for the normal azoturia is too large; in France it is given as twenty-one grammes. 2. Azoturia is proportional to the kind of diet. 3. A patient who is not fed, or who vomits his food, has hypo-azturia, no matter what his disease. 4. Cancers may be associated with hypo-azoturia. Rommelaere admits the force of the first two objections, though he thinks his own conclusions are not perceptibly altered thereby. Theoretically there are objections, but not practically. He adduces evidence to show that the degree of azoturia is not in direct relation with the quality and quantity of the food in acute diseases, nor even in chronic affections.

The Treatment of Lithæmia.

If asked how he would manage a case of lithæmia, Mr. Charles G. Stockton tells us in the *Buffalo Med. and Surg. Jour.* for February that he would answer: avoid quinine; look carefully after gastro-intestinal catarrh; keep open all the sewers of the body, including the liver; be most mindful of the primary digestion, and suit the diet to the case; using, if needed, pepsin and hydrochloric acid with albuminoids, vegetable diastase with starches, and extract of pancreas with milk and the fats, after the admirable plan of Roberts, of Manchester. And finally, the most important and most neglected agent of all, oxygen, should be gotten into the body. Do this by massage, which will improve the capillary circulation and hasten the lymph stream; by inhalation of oxygen, which promises much in this direction; by change of climate, or, if the case is not urgent, enjoin as far as practicable, an active out-of-door life, with horseback riding; for if there is anything that is truly anti-lithæmic, exercising, exhilarating, tingling a man into the belief that he is related to the gods, that thing is equination.

Pregnancy Mistaken for Cysto-sarcoma.

From Tassy, in Roumania, the following case is reported:

A peasant woman, twenty-five years old, who had had already seven children, and who had had no sexual connection with her husband for more than four years, felt herself pregnant several months after an illegitimate coition. To hide her pregnancy from her husband, she simulated violent pains in her abdomen, the cause of which was a tumor enlarging her belly, and went to Tassy, into the Saint Spiridion Hospital (not into the lying-in hospital). Here was diagnosticated a cysto-sarcoma of the right ligamentum latum, and laparotomy with consequent incision of the presumed cyst was performed. Instead of a cysto-sarcoma, they found a child of seven months, which remained living for some hours. The mother died on the seventh day. The respective physicians have been drawn to account, and the operator removed from his office.

Feeding by the Rectum.

The following formulæ for this purpose are given in *The Practitioner*, Dec., 1885:

For peptonized gruel: wheaten flour, oatmeal, arrowroot, sago, pearl barley, pea or lentil flour, gruel well boiled, thick and strong, Oj; put in a covered jug, cool to about 140° F., add liq. pancreatici ʒss. Keep warm under a cosey for two hours, boil and strain.

For peptonized milk gruel: thick hot gruel, cold milk, equal parts. To each pint add liq. pancreatici ʒij–iij., and sodii bicarb. grs. xx. Keep warm in covered jug for two hours; boil for a few minutes and strain.

For peptonized beef tea: half pound finely minced lean beef, water a pint, sodii bicarb. grs. xx.; simmer for one hour and half; cool to 140° F.; add liq. pancreatici ʒss. Keep warm under cosey for two hours; occasionally shake. Decant liquid portion and boil for five minutes.

When Not to Operate in Empyema.

This is a question that it is not always easy to decide, but that there are some cases wherein an operation is contra-indicated we all know. Thus Dr. Rickman J. Godlee tells us in the *Lancet*, January 16th, that in chronic phthisis an empyema may be present and apparently do no harm for a considerable period, but its evacuation may be followed, apparently as a result, by increased destructive changes in the lung; it may certainly, if the greatest care be not taken, be followed by increased constitutional disturbance from inflammation of the pleural surfaces. These cases should then, he thinks, be let alone as long as the presence of the fluid is not a source of inconvenience to the patient.

The Early Treatment of Convergent Strabismus.

Dr. W. Adams Frost concludes a paper in the *Brit. Med. Jour.*, January 16, 1886, by enunciating the following propositions:

1. The cure of a squint is important, not merely for cosmetic reasons, but because it is essential for binocular vision, and because, if neglected, the sight of the squinting eye will be very seriously impaired.

2. Treatment must on no account be postponed when the squint has ceased to be alternating.

3. The majority of cases, if seen sufficiently early, can be cured by correcting the hypermetropia.

Post-mortem Hyperpyrexia.

A singular case of this kind is reported by Dr. E. Underhill in the *Lancet*, January 16, 1886. The patient was a woman aged thirty-five, who, after labor, presented some evidences of a commencing mammary abscess. There was no evidence of organic disease, but she complained of feeling very hot, though she suffered no pain. She died, although but a few hours before, a favorable prognosis had been made. A few minutes after death the thermometer in the axilla registered 110.2° F., and two hours later, after the chest had been exposed to the atmosphere, it was 108° F.

Lanolin.

This new base for ointments is described and highly lauded by Dr. Oscar Leibrich in the *Brit. Med. Jour.*, January 16. It has a great capacity for absorbing water, more than 100 per cent. of which can be kneaded with it. The absorption of lanolin-sublimate ointment is so rapid that a few minutes after the application the characteristic metallic taste is observed. It is noteworthy also that this fat combines easily with glycerine, and that, in this combination, it can with ease be mixed with every other fat. In this way a great variety of agreeable cream-like ointments can be produced.

Diagnosis of Gonorrhœa in a Female.

The *Jour. Cut. and Ven. Diseases* tells us that Dr. Martineau claims that a specific may be distinguished from a simple vaginal discharge by the simple expedient of using a piece of litmus paper. In the specific form the reaction is always acid, while in the simple form it is always alkaline. The same test is also of value in cases of rape, in deciding whether the person who committed the crime was then suffering from gonorrhœa, as the vaginal discharge proceeding from this cause would be acid.

Salicylate of Sodium in Pericarditis.

Dr. Da Costa tells us that he is losing confidence in the power of the salicylates to prevent or cure the heart complications of rheumatism, and he gives a decided preference to the alkaline treatment; yet, on the other hand, Dr. Samuel L. Abbott states in the *Boston Medical and Surgical Journal*, January 21, 1886, that while the cases he offers are too few to generalize from, yet he cannot resist the conviction that the drug exerted a decided influence on the disease.

Correspondence.

BERLIN CORRESPONDENCE.

A New Method of Treatment of Tuberculosis of the Lungs.

Eds. Med. and Surg. Reporter:

Well, then, the year would have a good beginning—with a new treatment of chronic tuberculosis of the lungs and chronic bronchitis—if only *new* and *approved* were also always identical. Max Reichert, at Rostock has, several years ago already, healed tuberculous ulcers of the larynx with injections into the throat of a two per cent. solution of chloride of zinc. These results laid the idea before him if it would not be possible to influence the tuberculosis of the lungs through a similar local treatment. With the inhalation of medicinal vapors, the intended purpose is not obtained, because the

inhaled quantities are too small; the penetration of medicaments in the shape of powders into the lungs the author does not think very possible, but, on the contrary, he believes the process which he explains more particularly in the *Archiv. für Klinische Medizin*, vol. 37, heft 5, worth further examination.

The method consists in injecting medical liquids directly through the larynx into the trachea and the bronchi of the affected side of the lungs. Already six years ago this method had been made use of in chronic bronchitis and bronchiectasis. The remedies used for injection were lime-water, a ¼ to ½ per cent. solution of chloride of zinc, ol. eucalypti (5 per cent., with water or glycerin), ol. myrrhæ, ol. pini pumilionis, thymol ¼ per cent., ol. menth. pip., salicylic acid (up to ⅓ per cent.), salicylic acid 1.0 to 2.0 mixed with ol. menth. pip. 3 to 6.0, aq. dest. qu. suff. ad 2000. The best results have most likely been given by salicylic acid; also eucalyptus oil was of good effect.

The most important, and for the value of this method of treatment above all deciding question, was that, if and how far the liquid got into the lungs. The first made trial of the author in this respect is in that way, that as Leubuscher correctly mentions in *C. f. klin. M.*, No. 2, 1886, it is not very clear how he shall contribute anything to the decision or to the enlightening of the matter in question. In the lungs of a calf or sheep closed with cork a solution of methylic blue is injected by means of a syringe for the throat. Altogether eight injections were made. Afterwards methylic blue was found in all parts of the lungs. However, the author did not content himself with this one trial, but made use of two animals, a rabbit and a sheep, for the experimental decision of the said point. As far as the rabbit was concerned, he himself asserts that it is questionable if in general anything of the injected liquid came into the trachea; with the sheep, however, the case was different; here tracheotomy was made before, and twelve injections of crocus solution were made. It is true, the animal got dyspnœa, but the crocus solution was found after death in all parts of the lungs. The author, it is true, doubts in his demonstrations in his trial on animals (and that is no more than justified — L. C.); but, nevertheless, he thinks it undoubted that in man these injections would get into the lungs. And why? The subjective sensation of the patients gives the principal proof for it. For instance, by injections of light oil of wine, the patient mentions a burning in the parts of the trachea; after a number of such injections a dyspnœa takes place, only perceptible to the patient, which objectively is cognoscible through a slight crackling. From the irritation caused by the injection, R. has never seen any harm. Especially with bleedings of the lungs, these injections of light oil of wines have a downright prophylactic, sooner styptic effect. The consequence of these injections is in the first place the regular emptying of the products of secretion, as well through the inclination to cough caused by the injections as also the solvent action of the water, and through the animation of the activity of secretion of the bronchial pituitous tunic. Then, further, the disinfecting and astringing, eventually the healing and cicatrizing, exciting action of the injected liquid, as far as this has got into the lungs. Finally, this liquid becomes also resorbed, and after having been taken up in the mass of moisture of the body will also be able to operate.

The observations of R. extend to 60 cases. Always a favorable result was to be observed. Already after a few days could be observed also in the more difficult cases a striking improvement of the general state of health. The expectoration became easier, cough more seldom, vomiting left off, breathing became freer, the appetite better, sleep more tranquil, and the fever generally less.

The examination of the tubercle bacillus the author has not been able to execute often enough to be able to fix the result of the treatment in this respect. As to the manner of the injections, it is to be remarked that they are executed best either in quiet breathing, or, best of all, about the end of the expiration. Yes, one shall even try to inject the liquid in the right or left bronchus by turning the syringe to the respective side. The sensation caused by the manipulation is insignificant, so that one can make up to six injections. Sometimes a slight difficulty in breathing takes place. The treatment of injection is especially then of advantage when coughing excretions, with or without hæmoptysis, are present, but not too extensive caverns, not too important infiltrations, but also then astonishing results are to be recorded. The duration of the treatment must last in easy cases from four to eight weeks; in more difficult, from two to four months.

If this new therapeutic procedure mentioned and made use of by R. may well be remarked as interesting enough to undergo, on the basis of a methodical examination, a further trial, yet the manner of the proceed-

ing, as preferred by R., must be thoroughly and decidedly refused. The task to be solved before the therapeutic application was, conformably to reason, that to examine if in general something of the injection liquid gets into the lungs, and if this is the case, where the liquid gets to. This proof is entirely wanting, and to denote it as found through the subjective sensation of the patient—that would be imprinting upon the whole method from the beginning the character of a hypothesis. L. C.

Another Case of Short Interval between Confinements.

Eds. Med. and Surg. Reporter:—

The case reported by Dr. L. N. Davis, or rather by Dr. I. N. Trent, in your recent issue, page 192, reminds me of one—somewhat similar—in my own experience. My case may not be the shortest on record, although as close to it as it can be, but I think it as of much more interest, from the fact also that four children have been born within three years, at full term, and single births each time.

In looking over my obstetrical record, I find the case is that of Mrs. B., aged 17, whom I delivered for the first time March 5, 1883. In January 8, 1884, I attended her once more in her second confinement. Again in December 31, of the same year, I attended her in her third confinement. Finally, I delivered her again for the fourth time, November 18, 1885, of a fine and only girl. The case is remarkable for the short interval between each confinement, also for the young age of the lady, who at the age of twenty is already the mother of four children. On the other hand, she enjoys good health, has grown stout, and in fact, as I told her, "it seems to agree with her."

Supernumerary Fingers.

Eds. Med. and Surg. Reporter:

On September 8th, 1885, Mrs. S., a colored lady, was delivered of a female child, that was well formed and in every respect natural except the hands, which had an extra finger, or rather part of a finger, on each hand. The attachment was at the union of the first and second phalanges, on the outer surface. The attachment was by a small pedicle, one-eighth of an inch, the other one-fourth of an inch wide. The extra fingers were about one-half inch long, and had a nail and one phalanx on each. I removed them by clipping the pedicle; one bled considerably, and had to be bandaged to stop it, the other bled but a drop or so.

Upon inquiry I found this to have been the first case in the family, although the mother expected it, and was not surprised at the discovery. She related that her mother, two sisters, and two first cousins, had two supernumerary fingers; one aunt on her mother's side had but one. All were attached at the same point, as near as she could recollect. J. L. Geyer, M. D.
Norwich, O.

Sour Milk in Atonic Dyspepsia.

Eds. Med. and Surg. Reporter;

As Dr. W. O'Neill reported a case of atonic dyspepsia (in the Reporter of January 9) treated with sour milk, and having used it for the past eight years, I thought I would give you my experience. The first time that I ever used it was in 1877, after all other treatment had failed. I prescribed buttermilk and sour milk, one pint at each meal, instead of tea and coffee; and after the use of it for one week, the patient, a woman, felt much better, and I continued the buttermilk for one year, and she has not had a return of the dyspepsia up to the present time. I have since treated over thirty cases with the same result.

G. C. Wallace, M. D.
Rock Rapids, Iowa.

News and Miscellany.

Early Puberty.

A curious case of early puberty was shown by Mr. Bruce Clarke at the meeting of the Pathological Society of London on January 18th. A large muscular boy, apparently ten or twelve years old, came under treatment on account of bowing of the tibiæ due to rickets, and the parents made the astonishing statement that he was born on May 17, 1882, a statement subsequently confirmed by a reference to the birth-certificate preserved at Somerset House. He was three feet eight and a half inches high, and weighed four stone six pounds. There was some down on his cheek, and, though there was no hair on the chest or in the armpits, he was as hairy as a man about the pubes and in the perineum. His penis was as large as a man's, and was noticed to be erect every morning, though the testicles were rather smaller than those of an adult. The pomum Adami was

well developed, and his voice was cracked like that of a boy losing his "childish treble." The development of his brain, however, had not kept pace with the growth of his body, and his mental state was about that of a child of his years. The girth of the head round the occipital and frontal protuberances was twenty-one inches, which is certainly not very small for his bulk. It is interesting to note that, in spite of the great development of his sexual organs, he has never given any evidence of sexual desire, and that no seminal emissions are known to have occurred. The boy was the third child in a family of five, and he was bigger than the eldest child, who was over seven years old. He was suckled for nine months. At about one year of age he began to grow rapidly and to eat voraciously, so that nothing seemed to satisfy him. Hair began to grow on the pubes, and before he was a year and a half old, he was as hairy as a man. At about this time this very rapid rate of growth ceased, and since then his mother thinks he has only grown with ordinary rapidity. Mr. Bruce Clarke performed osteotomy on the bowed tibiæ, and the boy made a good recovery. A few cases are on record where puberty developed between the ages of two and three years, but Mr. Clarke informs us that he has been unable to find any other case recorded where it developed before eighteen months of age.

A Novel Consultation.

A writer in an exchange says: We were about three miles from Natchez, when we heard a great shouting and wailing in a negro's cabin by the roadside, and it was decided to dismount and go in. It was a tumble-down structure with but a single room, and into this were crowded sixteen or eighteen colored people, mostly of the female sex. On a heap of straw on the clay floor was a sick woman. She was rolling her eyes and writhing as if suffering great pain. When asked what ailed her, an old white-haired negro, who was called "doctor" by the others, replied: "Dat's jist what we doan' agree on. Some says it's de bilyus colic, an' some says it's de gallopin' consumpshun." "Why, man, something ought to be done for her right away." "'Zactly, sah—'zactly, an' Ize de doctah dat would like take right hold ob the case." "But why don't you! "Kase Ize boxed up, sah. I nebber gin the same medicine fur gallopin' consumpshun dat I do for bilyus colic, an' until we kin decide on de ailment I doan' dare go ahead." We were on our horses and ready to move off when the old man came out with a happier look on his face and said: "Gem'len, we has sorter took a vote on it, an' we has declared it rheumatism by one majority. Ize gwine right at it to heat de bricks an' gin her an all-night sweat."

Uneducated Druggists.

In reference to the necessity for state pharmacy laws in New York, the *Pharmaceutical Record* gives the following telephone conversation:

Central — "Hallo, Central! Give me Dr. B."

Pill-Grinder—"Halloh, Dr. B., is that you?"

Doctor—"Yes; what is it?"

Pill-Grinder—"I have a prescription of yours; have the first article, the second I can make if you are in no hurry, but the last article on it I am sure I cannot get."

Doctor—"Well, what is it? Read it."

Pill-Grinder—"The first article is sulph. morphine."

Doctor—"That's all right; what is next?"

Pill-Grinder—"It reads 'ung. pet.'"

Doctor—"Never mind, take cosmoline."

Pill-Grinder—"But, Doctor, the next article I am sure I cannot get in the city."

Doctor—"Well, go ahead and read it."

Pill-Grinder—"It reads, 'bene admisce.'"

Doctor—"Oh, never mind; just mix it well and thoroughly."

Query—Where is your State Pharmacy Law?

Echo Answers—Where?

Succession Duties Claimed on a Surgeon's Fee.

A medical man at Liege having to perform a serious operation on a lady, was asked his fee, and was offered it in advance. This, however, he declined. The result of the operation was unfavorable. After the patient's death the fee was paid by the family without any objection. Some time afterwards the surgeon received a letter from the notary of the Public Revenue Department, stating that the Administration of Finance "declined to recognize the fee, as, considering the position of the patient, it was exorbitant," and demanding succession duty on the whole. He added that if a lawsuit was to be avoided, a detailed circumstantial account must be furnished. The editor of the Belgian medical journal, to whom these particulars have been supplied, says that he never before heard of a revenue officer

claiming to interfere between a medical man and his patient about the amount of the fee.

Staufer's Instruments.

Among the numerous instruments devised for use in gynæcological cases, those manufactured of hard rubber by the Staufer process deserve to attract the attention of physicians by their cleanliness, durability, and adaptation to their purpose. From several recent letters before us we may quote the experience of those who have used them. Dr. D. A. Phillips, of Pa., writes: "The purchase of Staufer's uterine supporter effected through you has proved to be the most satisfactory one I ever made. The instrument leaves nothing to be desired." Dr. E. Cowan, of Mississippi, says: "The Staufer belts and cups give universal satisfaction."

A descriptive catalogue, illustrated, will be mailed on application to this office.

A Fever Swamp in Africa.

The *Medical Summary* says that Bathurst, on the river Gambia, seems to be a place blessed with any amount of inducements for travelers. Listen to one of them: We have shipwrecks, fevers, ants, ulcers, and malaria, which never fail us. The soil is loaded with it, the ships which visit our coast are loaded with it. Our houses are impregnated with it, and we have it in almost every form, and with every complication, all those known to medical science, besides a host which have yet to be added. Artemus Ward said he was very well satisfied to have his wife's relations go to the war and fight and die for our dearly loved gridiron or flag. We say how happy we should be if our mother-in-law would go to Bathurst. But then it might be hard on the Bathurstians, if any are left in that delightful climate.

Preventive Inoculation by a Russian Priest.

From the *Canadian Practitioner* we learn that a Siberian journal states that in 1868, when the plague was killing all the cattle in the country, Father Andrew Joakimansky, of the Troïtzky village, resorted to a desperate means in order to save his cows. He got some blood from a dying cow, saturated threads with that blood, and passed these threads through the ears of the healthy cows, numbering eleven. At the place where the ears were punctured there appeared tumors of the size of pigeon-eggs. In a short time these tumors disappeared, and the cows remained alive and healthy, though the rest of the cattle of that village perished.

New Pharmaceutical Preparations.

Hydronaphthol.

This is one of the same class of organic compounds as phenyl, and possesses similar antiseptic and detergent properties. It promises to have a wide use in surgery and sanitation. An excellent preparation of it is offered by Messrs. Seabury & Johnson, New York.

Hollow Suppositories.

The experience of every year emphasizes the advantages of rectal medication over any other method in numerous cases. Its details have been vastly facilitated by the invention of hollow suppositories, prepared of pure cacao butter and with self-sealing stoppers. This happy device is the ingenious production of the firm of Hall & Ruckel, 218 Greenwich street, N. Y., who furnish these suppositories in a great variety of forms and sizes.

A Tax on Burials.

The health authorities of Newtown, New York, where many of the large cemeteries connected with the city of New York are situated, have decided to refuse a burial permit without the payment of a dollar. The object of this is to raise money for the expenses of the town, as so much land is occupied by the cemeteries that it makes the taxes on other property very high. The undertakers are intending to fight the charge, as they say that it is really a tax upon burials, which the law does not permit. The matter is an interesting one, and not very certain of solution. A test suit will be brought to settle the question.

The Extent of Sulphur in Lighting Gas.

Pettenkofer concludes an opinion about the contents of sulphur in lighting gas with the words: "I can therefore pronounce with all precision, that it is, as well from hygienic as from a chemico-technical point of view, without any importance if lighting gas, free of hydrothionic acid, contains 0.2, or 0.5, or even 0.7 sulphur per cubic meter. The consumer of gas has never to expect a profit of this hunt after sulphuret of carbon; him it can only interest that the gas is free of hydrothianic acid, and that it possesses the stipulated power of light."

Association of Physicians and Pathologists.

The following circular explains itself:

PHILADELPHIA, February 15, 1886.

DEAR DOCTOR:—

In view of the undoubted advances which have everywhere followed in the different departments of medicine, the formation of special societies devoted to their interests, and in view of the fact that each one of the natural divisions of medicine, except those of general medicine and pathology, is represented in this country by a special society, it has occurred to some members of the profession that a similar Association of Physicians and Pathologists is desirable.

Accordingly, two preliminary meetings were held in New York City on October 10 and December 29, respectively, at which the matter was thoroughly discussed, and, after a general expression of opinion, it was finally decided:

1. To form an Association of Physicians and Pathologists, of which the number of members shall be limited to one hundred (100).

2. To hold an annual meeting in the month of June in the city of Washington.

3. To hold the first meeting on Thursday and Friday, the 16th and 17th of June, 1886, with Dr. Francis Delafield, of New York City, as President.

The undersigned were appointed a committee to notify those who were selected as orig1nal members, and we accordingly have the honor to cordially invite you to join this Association, and to take part in the proceedings of the first meeting in Washington, as above stated.

FRANCIS MINOT, Boston (Chairman of the Committee).
WILLIAM H. DRAPER, New York City.
WILLIAM PEPPER, Philadelphia.
R. PALMER HOWARD, Montreal, Canada.
ALFRED L. LOOMIS, New York City.
WILLIAM H. WELCH, Baltimore, Md.
FRANCIS DELAFIELD, New York City.
JAMES TYSON, 1506 Spruce St., Philad'a, Sec'y of the Committee, to whom it is requested that you will send your answer.

Snake-bites and Rabies.

The *Lancet*, January 16, tells us that the curious local traditions that are handed down from one generation to another are sometimes of much interest, and especially those bearing on the treatment of snake-bites and other accidental occurrences likely to prove fatal. In some of the heath countries a general notion prevails that the bite of a yellow or black adder is best combated by the rubbing in of some of the fat of an adder, and also by giving some of the grease internally. A lay correspondent, referring to an article in last week's *Lancet* by Surgeon-Major Roy, suggesting that the poison of the cobra may prove to be an antidote for rabies, says that it is a curious fact that in Wales there is a belief among the common people that a dog that has been bitten by an adder will never be subject to hydrophobia. When Sir Thomas Watson was asked his opinion on this subject, he said: "I agree with you in inability to see how this could be proved; or how, if proved, it could be practically utilized for the benefit of the human animal; such traditions are, however, always worth preserving." In the course of a case tried before the Tribunal of Correctional Police in Paris, it appeared that the carcass of a dog that had been slaughtered on account of rabies was thrown by scavengers on to a dust-heap, where it was devoured by cats and rats. A great number of the cats in the neighborhood of the places where the dust is shot from the municipal carts have been attacked with rabies.

Cider and Rheumatism.

The question has been several times discussed as to a supposed antagonism between the use of cider and rheumatism. Apropos of the question, Dr. T. Reuel Atkinson thus writes to the *Brit. Med. Jour.*:

Having lived for the last three years in this cider-drinking county *parexcellence*, will you allow me to say that, in my opinion, instead of there being any antagonism between cider and rheumatism, I am inclined to think that the one has a tendency, if anything, to cause the other. At any rate, rheumatism is, in this neighborhood, in one or other of its many varieties, a very common complaint; and the amount of cider consumed by the British workman about here is, especially in hot weather, something fabulous; many a man drinking his three or four gallons a day, and thinking nothing of it. Apropos of this matter, I have just come upon a passage taken from an old author who, writing of Herefordshire cider, says, after extolling its many virtues: "Lastly, for it excites the appetite, clears the stomach, strengthens the digestion, frees the kidneys from gravel and the bladder from stone. That which is made from pippins, duly ripened and well fermented, is an excellent remedy for consump-

tion." So it is very evident that cider is a remedy not to be despised, although not to be found in the British Pharmacopœia.

Railroad and Steamboat Fares to the American Medical Association Meeting at St. Louis.

The St. Louis Association of General Passenger and Ticket Agents, representing the railroads terminating at St. Louis, have announced that the tickets to the American Medical Association meeting, on May 4th, will be sold at the rate of one and one-third full fare for the round trip. The roads represented in the Association are Chicago, Burlington, and Quincy; Diamond Joe Line; Indianapolis and St. Louis; Louisville, Evansville, and St. Louis; Louisville and Nashville; Missouri Pacific; Ohio and Mississippi; St. Louis and Cairo Short Line; St. Louis and San Francisco; St. Louis, Keokuk, and Northwestern; St. Louis, Iron Mountain, and Southern; St. Louis and St. Paul Packet; Vandalia Line; Wabash, St. Louis, and Pacific.

The other railroads of the country have not as yet taken official action in the matter, but we are assured of the same rate being quoted by the majority.

Items.

—"Death from exposure," was the verdict recently rendered by a Helena (M. T.) jury on the body of a horse-thief who had been hanged by vigilantes.

—A letter from Berlin to the *Therapeutic Gazette* reports the case of a girl of eight with gonorrhœal rheumatism, communicated by connection with a boy of twelve.

—In our recent notice of the *St. Louis Medical Journal*, we should have added that Dr. Ohmann Dumesnil continues to be associated with its editorial supervision.

—"Ain't it time you paid me that five dollars?" "'Tain't due." "But you promised to pay me when you got back from New York." "Well, I hain't been there yet."

—Dr. Geo. H. Gilson, of Ills., writes us that on the 25th of January he delivered a colored girl, thirteen years of age, of twins, and that both mother and children survived.

—Mr. Sutro, of California, is about to build an aquarium 120 feet in diameter in the Bay of San Francisco. It will contain every sort of sea anemone, mosses, and shellfish.

—The English language consists of about 38,000 words, yet when a man is pulling on a tight boot or waiting for his wife to dress, he nearly always invents a few extra words to express his feelings.

—"What are the last teeth that come?" asked a Lynn teacher of her class in physiology.

"False teeth, mum," replied a boy who had just waked up on the back seat.

—Dr. N. Roe Bradner has established at Burlington, N. J., a private villa for the care of insane patients and others requiring quiet and medical supervision. We take pleasure in recommending Dr. Bradner's institution.

—A lunatic who escaped from the Hospital for the Insane at Buffalo two years ago, and has since been wandering over France and Great Britain, returned to his home in New York the other day perfectly cured, it is reported.

—Professor Semmola, of Naples, has received from the King of Italy the gold medal of "Public Merit," in recognition of his zeal and devotion in directing the sanitary service of the White Cross during the cholera epidemic of 1884.

—It is said that glycerine in its pure state should not be used for chapped hands, as it absorbs moisture from the skin, thus leaving it dry and liable to crack. When moderately diluted with water, however, glycerine is an excellent application.

—There is nothing new after all in the Pasteur method. It has been long known and tried in communities where it is the custom in the morning for a man to inoculate himself with a thimbleful of the dog that had bitten him the night before.

—A Montreal man lately sued a druggist for damage for having been deprived of work for several weeks in consequence of taking a poison sold him by mistake. The error was caused by the wholesaler, who had labeled the package wrongly before selling it to the druggist. The Court held, however, that the druggist should have verified the contents of the package, and gave judgment for $200 and costs.

—A Chicago firm is engaged in making bricks out of a mixture of sawdust and clay. They are subjected to a heavy pressure, burned like common brick, and in some way made waterproof. They measure 13 by 6 by 4 inches, and having two square holes running through them lengthwise, they weigh little more than common brick, although four times as large. They are laid between the outer and inner courses of a wall.

JENSEN'S PEPSIN TABLETS.—75 2½ grs. Tablets in each bottle, pleasantly flavored. Retail $1.00. All of it pure pepsin.

W. H. SCHIEFFELIN & CO'S.,

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

SENILE ENDOMETRITIS.*

BY B. F. BAER, M. D.,

Professor of Obstetrics and Gynecology in the Philadelphia Polyclinic.

Reported by William H. Morrison, M. D.

Gentlemen: The first patient whom I present to you this morning is Mrs. T. It is a case which I have shown before as an example of senile endometritis, which had resulted in hydrometra or retention of the serous fluid secreted by the utricular glands within the cavity of the uterus. This retention resulted from obstruction in the cervix. The menopause occurred ten months ago. When the patient first presented herself more than two years since, she had a bilateral laceration of the cervix. The whole fundus of the vagina was covered with granular tissue, and the surface was thickly studded with enlarged Nabothian glands or follicles. At that time she had a watery discharge from the vagina and pruritus vulvæ. She had also lost some flesh, and was considerably reduced in strength, but there had been no hemorrhage. These symptoms led me to suspect the possibility of beginning carcinoma. Examination, however, did not reveal the characteristic appearance of epithelioma, but showed a granular condition, the result of inflammation from the traumatism.

After several months of preparatory treatment, I operated on the lacerated cervix eighteen months ago. The preparatory treatment in a case like this consists, first, in the repeated puncture of the Nabothian or retention cysts. The orifices of some of the Nabothian follicles had been closed by the inflammatory process, and the continuance of the secretion had resulted in their over-distention. All over the surface were shot-like projections which were the result of distention of these follicles. There was also hypertrophy of the papillæ or looped veins, as well as of the inter-vascular tissue. Repeated scarification of the surface, which includes puncture of the distended follicles, is absolutely necessary before operation should be attempted in a case of this kind. Churchill's tincture of iodine, which is a saturated tincture, was also applied to this surface at short intervals, and on a few occasions a weak solution of the nitrate of silver was applied. The application of nitrate of silver week after week is properly a plan of treatment not so frequently resorted to now as formerly. The nitrate of silver will undoubtedly cause cicatrization quicker than any other method of treatment, but cicatrization is not to be desired where it can be avoided, for this does not restore the tissues to their natural condition. One of the greatest advances which have been made in uterine therapeutics is that which secures the healing of these surfaces without causing cicatricial contraction.

In a case like the present, the application of remedies should not be limited to the cervix. The cavity of the womb was also in a granular condition and the canal patulous; under these circumstances the medication should be carried into the cavity of the uterus. This is to be done not only for its local effect upon the surface, but also for its

*A clinical lecture delivered at the Hospital of the Philadelphia Polyclinic and College for Graduates in Medicine.

stimulating effect on the uterine muscular fibre, just on the same principle that an application of vinegar or other stimulant is made to the cavity of the uterus for the purpose of checking post-partum hemorrhage by inducing uterine contraction. In subinvolution, especially of recent date, where the uterus is still soft, I am sure that the application of the remedy to the cavity of the uterus for the purpose of stimulating it to contract and force the effete matter out, and of stimulating the pelvic circulation, is founded on a correct principle.

After continuing this preparatory treatment until the surface had healed and all the inflamed and distended follicles had been cured or destroyed, I operated on the cervix. It was necessary to dissect up some of the vaginal tissue to make a flap to cover the surface of the cervix, and to place fourteen sutures to secure proper coaptation of the parts. The result, so far as the cure of the laceration was concerned, was perfect. The cervix is now in a healthy condition, and yet the patient has not been entirely relieved of the distressing pain in the hypogastrium. As I have stated, the operation was performed eighteen months ago. She has been benefited, but the endometritis which existed previous to the operation has not been cured. She is now suffering with senile catarrh. This affects the utricular glands. The patient is 44 years of age, and ten months ago the menses were suppressed, and she thought that she was probably pregnant. The abdominal cavity became distended, and she had some nausea.

The symptoms which she now presents are mainly hypogastric pain which radiates to the back, and slight watery leucorrhœa; such pain is nearly always the result of irritation of the cavity of the uterus from some cause. Here it is the result of senile endometritis.

The question of course presents itself in the consideration of this case, did I operate too soon? Should I have waited until this catarrh had been cured? She had been under treatment five or six months, and the condition of the cervix had been decidedly improved. Should I have waited until the pain in the sacrum and hypogastrium had been entirely relieved? I think not. The congestion had been reduced, there was no exudation in the cellular tissue, and the uterus was movable. On the other hand, there were several reasons which I think rendered it advisable not to delay the operation. The patient was approaching that period of life at which cancer is most likely to develop; the cervix uteri was in a condition most favorable to the development of epithelioma; and she was losing flesh. There is no question that traumatic conditions such as this case presented predispose to carcinoma. I can not say that I have prevented the development of the disease in this case, but it certainly was acting on a correct principle to restore as soon as possible this surface to a condition of health.

Introducing the speculum, you see that the mucous membrane covering the cervix is healthy. When, however, I pass the sound, I find the uterine cavity patulous, tender, and vascular, for the instrument produces slight bleeding. All the cicatricial tissue was not dissected out of the canal. If I were to again operate upon this patient, I should dissect out all this tissue, disregarding the possibility of the two surfaces uniting. I have done this on several occasions since, and have never had the canal close up.

Two months ago I introduced the sound, and on withdrawing it about an ounce of serous fluid escaped. We had therefore hydrometra. I have injected carbolic acid into the cavity of this uterus, and on one occasion I injected ten drops of fuming nitric acid. She has not yet recovered, although she is always improved after an application, At the last visit, I dilated the contracted cervical canal, because it will not do to allow the os to close until the utricular glands have been made to undergo the senile involution natural to them, or have been destroyed. To-day the canal is quite patulous.

In a condition like this there is a possibility, indeed there is a probability, of doing too much in the way of treatment. We should give our remedies time to act. The object of treatment is to bring about senile involution, modify the secretion of the utricular glands, and remove the inflammatory process. Until that is accomplished, the patient will continue to have the symptoms which she has presented, viz., pain in the hypogastrium and back, and pruritus vulvæ.

NYMPHOMANIA.

Our next patient has given us the following history: She is 32 years of age, single. Puberty began at the age of thirteen; she has always suffered with dysmenorrhœa, the pain being intermittent and bearing down in character. It continues during the whole period, and is especially severe during the first day. Four years ago she began to have pain in the right iliac region. At times she has some leucorrhœa, although this is very slight. The pain in the right ovarian region

comes on suddenly, independent of the menstrual period. It is not radiating, but dull, aching, and deep-seated. Four years ago she became pregnant, and abortion was induced at the third month. She dates this pain from that occurrence.

There is another point in this case to which I desire to call attention. When nine or ten years of age she began to practice masturbation or onanism as a result of imitation. She informed us when puberty occurred the desire and habit became much worse, and she has continued it until a few months ago. It had become a mania with her, and when she was sent to me her mental state had become much depressed. With this, as I have said, there was dysmenorrhœa and deep-seated aching pain in the region of the right ovary.

The pain which she complained of did not indicate ovarian disease, for it was not radiating. Pain, the result of ovarian disease, is, as a rule, sharp in character, following the direction of the genito-crural nerve, affecting the groin, labium majorum, and anterior portion of the limb of the affected side. The deep-seated, fixed character of this pain led me to exclude ovarian disease. Such pain should always impress you with the probability of cellulitis, for in pelvic peritonitis the pain is more likely to be sharp and partake of the character of ovarian neuralgia, more diffused than the latter, however.

A vaginal examination to-day shows that the cervix is tilted forwards, but this does not necessarily indicate a retroversion, for in a sharp anteflexion of the neck and body of the womb, the former would point forwards. A tumor is felt posteriorly, and the body of the uterus cannot be felt by bimanual examination. These are, however, not enough to positively prove that the mass felt posteriorly is the body of the uterus. Passing the finger over the posterior surface of the tumor, the neck is found to be continuous with the mass behind, and a slight angle of flexion is distinctly felt. There might be an apparent angle of flexion caused by a small fibroid tumor projecting from the posterior surface of the uterus or from a mass of lymph which was adherent to the organ, but the existence of the physical signs mentioned make it almost certain that the mass felt is the retroflexed uterus. Of course, the crucial test would be the passage of the sound, but that is unnecessary here for the purpose of forming a diagnosis. As a rule, it is not necessary to pass the sound for the diagnosis of displacement.

When this woman came under my care some nine months ago, I found the cervix tilted against the anterior wall of the vagina. It felt velvety, and its epithelium had disappeared. It was much enlarged, and several Nabothian follicles were scattered over the surface. The os was narrow, and there was apparently cicatricial tissue, as though some injury had been done. The uterus was almost immovably fixed by an exudation of lymph in the right broad ligament, and it was retroflexed. To-day we find the organ quite mobile; the cervix can be pushed far back into the fundus of the vagina, and the body is then elevated so as to look anteriorly.

This woman has practically been made well by the treatment pursued. The uterus is, however, still retroflexed. Yet the symptoms have all subsided. Shall I let the uterus alone, or adjust a pessary for the purpose of forcing it into a position of anteversion? Emphatically, no. That would, I think, be bad practice in this case. My plan would be to keep the patient under observation, and if there is a return of the symptoms, renew the treatment pursued so successfully before. Again, even if I should introduce a pessary, I could not make the uterus remain forward with an instrument which it would be proper to employ. It would produce ulceration of the posterior wall of the vagina from pressure. The use of a pessary sufficiently large to carry the cervix back, and force the body forward, would produce more injury than would follow from permitting the uterus to remain in its present position. How do we know that the uterus has not always occupied a retroverted position in this patient? We do meet with such cases. I find when I carry the body of the uterus forward, that the left broad ligament, as well as the right, is somewhat contracted, and that the utero-sacral ligaments are also contracted. These ligaments would be pressed upon by a pessary, so that harm would follow, or they would resist, so that the posterior bar would be made to press into the angle of flexion. This action of the pessary is always to be deprecated. If the attempt were made to span the angle of flexion with a large pessary, it would have to be supported against the pubic bone behind the pubic arch, and it would then make injurious pressure on the utero-sacral ligaments, as well as upon the other tissues. The leading symptom for which this woman consulted me was the nymphomania. This was exaggerated by the inflammation and congestion of the pelvic

organs, and the indications were to relieve this condition. I began the treatment by prescribing thirty grains of bromide of potassium morning and evening. At first I made no local application to the cervix, but as there was excoriation of the organ as well as pelvic pain, I ordered a suppository containing morphia, belladonna, and tannic acid. When she returned in the course of four or five days, she felt better. The manipulation of the uterus at the first visit stimulated absorption to a certain extent, and at the second visit the parts were more mobile. I then began with the local application of iodine every five days, making gentle massage of the rigid tissues previous to the painting. Soon the uterus and other tissues were so mobile that I felt justified in passing the sound and using it as a repositor, gently elevating the organ for the purpose of stretching the adhesions. As soon as all tenderness had subsided, I passed my steel dilator through the narrow and rigid cervical canal and merely separated the blades. The enlarged Nabothian follicles were punctured. This was repeated at each office visit, and was done for the purpose of stimulating the pelvic and uterine circulation and to render the canal more patulous, as well as to cause the uterus to assume a more correct position. She was also soon placed upon the following:

℞. Hydrarg. chloridi corrosivi, gr. j.
Liquor arsenici chloridi, ʒj.
Tr. ferri chloridi,
Acid. hydrochloric diluti, āā ʒiv.
Syrupi simplicis, ℥ij.
Aquæ, q. s., ad., ℥vj.
M. Sig.—A dessertspoonful, well diluted, after each meal.

This remedy is known as the mixture of the four chlorides, and was first used, I believe, by Tilt, of London, and introduced to the profession of Philadelphia by the late Dr. A. H. Smith. It has, I believe, antiplastic powers. It is at least a good alterative tonic, and I have prescribed it largely during the past four or five years.

The nymphomania has been entirely cured, for the time at least. At one time she was so well that I dismissed her with the injunction that she must return at once if the old symptoms reappeared, and she is here to-day in obedience to that advice.

I find the local condition about as it was when last examined, and I shall simply paint the cervix and ligament with iodine, and ask her to return in a week. I think she is practically well. Certainly an operation of magnitude, öophorectomy, which she once begged me to perform, would not be justifiable in this case, for the patient has recovered without it. It seems as though the treatment had the power of exploding or dispelling the force, whatever it may be, which exerts itself upon the sexual centre to produce the erethism.

FIBROID TUMOR OF THE UTERUS.

I will briefly refer to the next patient, as my allotted hour has almost expired. She is fifty years of age, colored, married. She has had two children, the first twenty-five years ago, the second two years later. She had two miscarriages about twenty years ago. Her labors were natural, but she has not been well since the birth of the first child. She had bearing-down pains in the hypogastrium and in the back, with mucous leucorrhœa. The menopause occurred two years ago, but for four or five years before that the menstrual periods were profuse, and returned every two or three weeks. During the last two years she has had on several occasions a slight bloody flow. Since the occurrence of the menopause, there has been a leucorrhœal discharge, but of a different character from that which she had before the cessation of the menses. It is now watery and produces what it did not produce before, viz., a pruritus vulvæ. This was the leading symptom which drove her to consult us. During the time when the leucorrhœa is worse, she has flushes of heat and the abdomen becomes distended with gas. She states that five years ago she discovered a lump in the hypogastrium, and it has been growing steadily since then. As I have said, the menopause occurred two years ago. If this were a fibroid tumor, we should have expected it to diminish instead of increasing in size. If it were an ovarian tumor, it is more than likely that in five years it would have reached such a size as to require operation, or to have resulted in death before this time. It is probable that this is a fibroid tumor, for she is a colored woman, and because she has not borne a child for twenty-three years. A black skin and sterility are two predisposing causes of fibroid tumors. As an offset, however, they are a protection against cancer to a very great degree. Thus are evils balanced. This tumor has grown very slowly, and now it is not much larger than when first discovered, if her statement as to its size at that time is correct. This is in favor of fibroid tumor. It is probable, however, that the growth is smaller than two years ago. The rule is that after the ovarian stimulus to the pelvic

congestion has ceased, fibroid tumors decrease in size, and if they go on enlarging the hemorrhage continues. Here the hemorrhage has ceased, and we must infer that her observation is at fault, that the tumor has not increased in size, but rather the reverse This inference is strengthened by the physical signs elicited.

Vaginal examination shows a very hard, nodular mass in Douglas's pouch. The cervix is pushed forward, and the anterior lip seems to be elongated. Placing the hand on the abdomen, a firm, nodulated tumor is felt. This seems to be connected with the uterus and with the mass in Douglas's pouch, for movement of the tumor produces movement of the uterus and of this mass. The sound enters the uterus a distance of five inches, and movement of the tumor causes the sound to move.

From these points we have come to the conclusion that the tumor is a subperitoneal fibroid rather than interstitial, but interstitial to a large extent, because the uterus is so long. In purely subperitoneal tumors, the uterus does not measure much over three inches. In interstitial tumors, the uterine cavity reaches its greatest length, six or seven inches, sometimes even eight inches. With submucous tumors, the hemorrhage is usually greatest, but the uterus, as a rule, is not so large.

What were the indications for the treatment of this patient? An operation was, of course, out of the question for the time. This fibroid could not be removed without extirpating the uterus. This is a grave operation and only justifiable when the patient's existence is rendered unendurable.

The symptoms for which she sought relief were the pruritus, the distention of the abdomen and the flushes of heat, all of which were due to the irritation of the uterine cavity, which resulted in the watery discharge from the utricular glands. The indications were to modify the secretion from these glands, in the hope of relieving the aggravating symptoms and of still further reducing the size of the tumor. Finding the uterine cavity enlarged and tender, I began by making applications to the interior of the uterus. I injected through the intra-uterine syringe a mixture containing equal parts of pure carbolic acid and a saturated tincture of iodine. This was repeated weekly for five or six weeks. For internal administration a mixture of the fluid extract of ergot and the tincture of nux vomica, equal parts, was ordered, forty drops being given after meals. I have never seen any bad effects from these large doses of nux vomica, and I believe that it enhances the effects of the ergot. I also gave chloride of ammonium in ten-grain doses. This I have found to be decidedly the best remedy for the relief of the flushes of heat, which is often a distressing symptom at this period of life.

The result has been most happy. The symptoms have been relieved, and the patient states that she is free from the pruritus vulvæ and the flushes, and that the periodical distension of the abdomen from flatus has disappeared. She has resumed her occupation. It will, of course, be necessary to keep her under observation and to renew the treatment from time to time, until the tumor ceases to be a source of irritation.

Communications.

THE DISPOSAL OF SEWAGE, AND THE PROTECTION OF STREAMS USED AS SOURCES OF WATER SUPPLY.*

BY GEORGE E. WARING, JR.,

Of Newport, R. I.

One of the most important questions now claiming attention, in connection with the sanitary condition of houses and towns, relates to the manner of getting rid of the foul constituents of the liquid effluent in such a way as to prevent annoyance from odors, danger from the development of infection, and the contamination of water-courses and harbors. The difficulties presented have always existed, and the ill-effects of ordinary methods have always been known. It is only since attention has been called to the relation of the foul effluent of house and town drainage to the spread of diseases that the difficulty has been generally recognized, and only since the modern growth of the larger towns that its dangers have been fully apprehended.

In a few fortunate cases, such as those of towns discharging their effluent into great rivers like the Mississippi, the remedy is provided by the volume of the stream to which the sewage is added. In London, the Thames has become so foul that the Royal Commission which recently investigated the matter pronounced the system of outflow there established to be "a disgrace to the metropolis and to civilization." In Paris, the discharge of the great collecting sewers into the Seine has produced a condition that is no longer

*Read before the College of Physicians of Philadelphia.

tolerable. Were the houses and streets of Philadelphia drained in accordance with modern ideas of decency and efficiency, the condition of the Delaware would perhaps become little better than that of the Schuylkill. The great addition to the tidal volume of the harbor of New York, due to the inpouring through the East river of the higher tide of Long Island Sound, mitigates, but does not remedy, the foul condition due to the discharge of the city's wastes along its whole border. In short, all considerable communities in this country and in Europe are confronted to-day by a problem which it is absolutely necessary to solve. In one way or another the waste organic matter of our domestic life and of our industries must be withheld from the waters into which our sewers discharge.

I propose to notice, only in passing, what may be called the more artificial means for accomplishing this result; that is, the chemical and mechanical methods of precipitation, decantation, and distillation. There are instances in Great Britain, and on the Continent of Europe, where the difficulty of securing a sufficient area of land for what we may regard as the more natural treatment is so great that there is no choice but to resort to these more costly and less efficient processes.

It is possible, by an addition of the salts of iron and other salts, of milk of lime, of comminuted clay, etc., to cause the deposition of nearly or quite all of the suspended impurities of sewage. The deposit or sludge thus formed is sometimes treated by filtration, drying, filter-pressing, etc., in such a manner as to become available as manure for use on lands not too far removed.

In connection with the Liernur system of pneumatic removal in Holland, an ingenious plan has been devised by which the solid parts of the slightly diluted effluent are recovered by evaporation *in vacuo*. In Germany, other more elaborate processes, including the distillation of the purified effluent, have been measurably successful in the production of the salts of ammonia for commercial use, and of a residuum of some manurial value.

It seems hardly worth while, in the short space here at my disposal, to do more than to refer to these processes, which, however important under favoring circumstances, are not suited to conditions prevailing almost universally in this country. There is probably no town in the United States where any treatment of sewage is desirable, where it will not be cheaper and more simple to overcome the difficulty by the aid of surface or sub-surface irrigation or by more concentrated filtration—filtration, in greater or less degree, being an essential element of all irrigation. This application to the soil is not only cheaper and more simple, but is also more effective. No chemical or mechanical treatment has thus far been devised which produces an effluent so entirely free from organic impurity and from the lower forms of life as that which is produced by properly regulated agricultural disposal.

We have been, until recently, quite in the dark as to the processes by which organic wastes are destroyed after application to the ground. We seem now to have some positive knowledge on the subject—knowledge due largely to the investigations of Dr. Frankland in England, and of Schloesing and Muntz in Paris—these investigations being an application of knowledge derived from the biological investigations of late years.

It may now be accepted as a demonstrated fact, that the various processes of oxidation and nitrification by which organic impurities in the soil are reduced to their mineral elements or to elementary salts, are due to, or are largely aided by, the reproduction and growth of bacterial life. This was especially well demonstrated in the Paris experiments, by the fact that, while sewage, filtered through a suitable soil confined in a cylinder two metres high, the liquid being applied with intervening periods for aëration, was deprived of its impurities and allowed to pass out at the bottom of the column as pure water, the process being accompanied by a great increase of bacterial growth; the impregnation of the soil with the fumes of chloroform was sufficient, by arresting bacterial activity, to allow the sewage to be discharged as impure as it was received. Ample confirmation of the obvious conclusion was found in the fact that after the chloroform had entirely escaped from the pores of the soil, the purifying effect was fully restored.

Roughly speaking, or rather practically speaking, the process is this: When sewage is applied to the soil its impurities are filtered out and are attached to, or involved with the particles of the soil. The water thus purified descends to the lower strata—to the under-drains or other means of outlet. As the water descends, fresh volumes of air enter and furnish oxygen which it is the office and the means of life of the *bacterium termo* to combine with the retained impurities. The resultant product is fully decom-

posed matter, available for the use of plants or for innocuous removal in solution. There is much in the way of detail concerning the processes involved yet to be discovered, and investigation is active in this direction. Enough is now known to constitute the basis of a rational theory applicable to the practical processes we are considering. These processes have long been employed with more or less completeness, and with corresponding perfect or imperfect results.

It would be a fair summing up of the whole case to say that we now know, by well-established theory and by ample practice extending over more than twenty years, that we have in the soil a universally-available agent for the safe, inoffensive, and complete destruction of everything in the way of organic waste that we may deliver to it in a proper manner.

As we look over the field of practice, beginning with the Craigentinney Meadows at Edinburgh, which have been irrigated with sewage for more than a century, and ending with the most complete modern examples, we find the greatest conceivable variety of conditions, and a great variety of results. There are more than one hundred sewage farms in England, to which are applied the effluent of as many towns, large and small. Some of them have been carefully arranged, and are fed by sewers which deliver the sewage to them in a very early stage of decomposition, and where the great bulk of the storm water is diverted to other outlets. On these the best results are obtained. In other cases the attempt is made to purify the whole outflow, storm water and all, with the natural result that floods of storm water deluge the land at those times when it is already drenched by the heavy downfall and is incapable of absorbing more water. Here the result is far from satisfactory.

In Germany, sewage irrigation farms connected with the city of Berlin, with Dantzic, and with Breslau, arranged in accordance with modern ideas on the subject, are all instances of notable success.

At Gennevilliers, where about one-fifth of the whole outflow of the sewers of Paris, about one-half of the dry-weather midsummer flow, is distributed over a very large area of thirsty and hitherto almost valueless sand and gravel, the result is excellent.

In our own country, we have as yet no instance, save the recent one of Pullman, Illinois, of a general system of sewage irrigation. The result there, according to all reports, is as good as it has been elsewhere.

I have recently had an opportunity of carrying out a rather complete system of sewage disposal in your near vicinity, in connection with the State Asylum for the Insane at Norristown. As I have endeavored there to work according to the best indications of modern experience, and as my efforts have been freely sustained by the Trustees of the Asylum, I know of no way in which I can better set forth what seems to me the best method for disposing of sewage than by describing, somewhat in detail, the work that has there been done and the result thus far achieved.

The Asylum is situated on high land in the northeastern suburbs of the city, on the water-shed of Stony Creek. The buildings include eight large pavilions, with the necessary administration buildings, kitchens, laundries, etc. The population of the institution is now not far from 1600. The consumption of water is not far from 150 gallons per head, daily, and all manner of organic waste, except the garbage which is fed to swine, must necessarily be disposed of through the system of house drains and sewers with which the institution is amply supplied.

As at first constructed, the system of drainage, delivering not only foul wastes but roof and surface water as well, discharged its contents through a large main sewer running in a southerly direction, entering a brook which delivers in a short distance and with a steep incline, into Stony Creek near the hospital station of the railroad.

Although the ample facilities for the drainage of such an institution afforded by Stony Creek had been a chief inducement offered by the city of Norristown for the location there of the Asylum, the buildings had not long been occupied before complaints were made of the gross fouling of the creek due to the hospital drainage.

Following the erroneous idea which is so prevalent, that the chief source of defilement in sewage is fæcal matter, two immense settling tanks were established in the grounds for the retention of these solids only, the effluent enriched by the products of their putrefaction overflowing into the sewer and running into the creek. As urine and kitchen wastes are quite as bad in their ultimate condition as is fæcal matter, and much more serious in amount, this process did not long satisfy the complainants, and an injunction was threatened to prevent the discharge of any sewage from the hospital into the stream. In consequence of this threat, the authorities engaged me to devise and carry

out some other system of relief. What has been done is as follows:

The old system of drains and sewers has been left as it was, to carry off the roof-water and surface-water from the courts, walks, etc., these finding their way into Stony creek through the old channel. A separate system of sewers, six inches in diameter, has been constructed in connection with all of the foul waste-pipes of the building, so that they carry all kitchen and laundry waste, bath and toilet waste, closet discharges, and dining-room and pantry sink waste, everything, in short, which contains foul refuse. For lack of sufficient appropriation, some changes that it was thought desirable to make in the interior plumbing of the buildings were not made. It was attempted to substitute water-closets with traps for the untrapped closets already in use. These latter have their outlets connected with ventilation pipes in which a strong current of air is maintained by the use of steam—a very expensive process. They are also flushed by automatic cisterns in such a way as to consume a very large volume of water. The trapped closets with independent flushing cisterns, to be worked by the use of the seat, would have effected considerable economy; but it was found that the odor produced during their use, especially in the morning when used in rapid succession, could not be kept out of the wards without the introduction of a new system of apartment ventilation. This experiment was therefore abandoned as too costly in construction, and the old method of forced downward ventilation continues, in spite of the cost of its maintenance.

The dining-room sinks were subject to the usual difficulty from the accumulation of grease. Such sinks as are to be retained were supplied with a flushing outlet, which is accomplishing a most satisfactory result. The same system was applied on a very large scale to the kitchen sink, which is so arranged that its outlet is ordinarily kept plugged. When discharged, from 50 to 100 gallons are delivered at a time through a 4-inch pipe; this sweeps all grease and other refuse rapidly forward, and constitutes an effective flush for the kitchen drain, which formerly gave trouble even with a large grease trap, and with the occasional introduction of a jet of steam.

The system of sewers described is brought together to a single main outlet six inches in diameter, constructed like the branch sewers of vitrified earthenware pipe. This main sewer delivers into one corner of an open tank 40 feet square and about 6 feet deep, built of brick, laid in and coated with Portland cement, and having a Portland cement concrete floor. It is probably absolutely tight. Immediately in front of the inlet (the mouth of the main sewer) there is a vertical iron screen, with one-half inch openings, for holding back paper, rags, a small part of the fecal matter, and the miscellaneous rubbish delivered from the buildings. In the corner of the tank, diagonally opposite the inlet, there is a vertical Rogers' field annular siphon, the overflow of its discharging limb, eight inches in diameter, being five feet above the floor of the tank. About a foot below the overflow level, and through the south wall of the tank, there is a 4-inch opening which is ordinarily kept plugged. At the bottom of the tank, and connected with the main discharging chamber outside, there is a pipe through the wall closed by a screw-gate.

The flush-tank, the largest I believe that has ever been constructed, has a capacity between its floor and its overflow point of 60,000 gallons. It occupies about two hours in discharging, and during this time about 15,000 gallons more flow in from the main sewer, so that the total amount discharged at each operation averages about 75,000 gallons.

The discharging siphon is so arranged that when sewage begins to overflow at the top of its discharging limb its outlet becomes sealed, its contained air is soon withdrawn, and it discharges, full bore, until the tank becomes empty, when air is taken, first at the inner end and then at the outlet end; the siphon "breaks," and nothing more can be discharged until the overflow begins again. The discharging chamber delivers into an 8-inch pipe which leads to the irrigation field.

In the course of the main drain, above the tank, there is a gate by which the flow can be diverted from the tank and sent through a by-pass directly to the 8-inch pipe. Below the tank there is another gate by which its discharge may be diverted to a truck-patch near by whenever sewage is required for irrigation there. Higher up in the truck-patch there is a sewage carrier which is connected with the 4-inch hole near the top of the tank. By a proper adjustment of these different arrangements sewage can be sent from the buildings directly to the irrigation field without going through the flush-tank, or can in like manner be diverted to the lower carrier of the truck-patch. By opening the gate at the bottom of the tank, sewage is allowed to flow out as it flows in, and can be sent in uniform moderate quantity to the irrigation

field or to the truck-patch. By removing the plug near the top of the flush-tank, the upper carrier of the truck-patch can be made to receive sewage for four or five hours, but as the entering stream is too large to be completely removed at this point, it in time reaches the overflow and starts the siphon, and the whole accumulation is discharged through this.

These truck-patch carriers, the by-pass, and the various gates, are incidents of the system and are intended only for occasional use; ordinarily, the discharge is in a strong flow through the main 8-inch pipe connecting with the irrigation field.

(*To be continued.*)

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. John H. Packard.

New Method of Applying Extension and Counter-Extension.

I will commence my lecture to-day, gentlemen, by demonstrating to you what I look upon as a very great improvement in the method of making extension and counter-extension in the treatment of fractures. You are familiar with the fact that in treating a fracture of the thigh, the ordinary method of making extension is by the use of long strips of plaster on either side of the limb, with a piece of wood in the end, and from it a cord passing through a pulley in an upright at the foot of the bed. Well, the method I propose to show you, I consider far superior to this. In my plan, instead of applying the plaster on either side of the limb, it is applied spirally. Now, you see I split a piece of adhesive plaster into two tails, the split extending from either end up to within about four inches of each other; thus we have a solid piece of plaster about four inches long, to each end of which there are two tails. In the centre of this solid piece I place a small piece of wood, and double the plaster over it. Now then, I place one of these sets of tails around the inner and one around the outer side of the leg, and wrap them about the ankle. I place them as low down as will insure me a good hold on the foot. Two similar strips are placed above, splints are then applied and strips of muslin passed through the loops formed by the pieces of wood; thus by tying the strips of muslin from above, coming over the superior angle of the splint, to the strip from below, coming over the lower margin of the splint, we can make any required degree of extension. We should be particular to have the splint come below the level of the foot. If the extension is too great, we can slacken up the strips and lessen it. If we desire a continuous tension, rubber bands can be used in place of the strips. For extension in fracture of the thigh, I take a piece of adhesive plaster about six feet long, and split as before. Then a block is placed in the centre, and I take first one strip and wind it spirally around the leg, then I do the same with the other. In this way we avoid all dangerous pressure, there is no wrinkling of the plaster to cause soreness, yet it holds so tightly that I could pull the man out of bed by these strips.

Caries of the Tibia.

I now show you a child with necrosis of the tibia. For fourteen weeks he has had some trouble with both limbs; one knee is stiff. I will etherize him, and see how far there is genuine anchylosis and how far this stiffness may be due merely to fibrous adhesions. You will find many cases of necrosis with joint-disease, and the question will come up as to how far should you go in breaking up adhesions, and when it will be better to let the joint recover with stiffness, and take the chances of its after usefulness. As a rule, I would say that it is better not to break up adhesions when there is any disease of the bone; it will then be better to let it get well in the deformed condition, and resort to apparatus to endeavor to correct the deformity. Sometimes we will be called upon to correct the deformity by subsequent operation, as in anchylosis at a right angle; such cases are comparatively rarely encountered, and it would seem to me that a person might as well have no leg as one bent at a right angle. In this case, the boy fell off some steps fourteen weeks ago, and bruised his right knee, and I imagine that the left must have been also injured, for here I see a scar which may have been due to the injury and may have been caused by the surgeon's knife, though I do not know of any operation having been performed here. I will remove the scab to see what we have here. I surely have some lesion of the bone, for my probe comes in contact with the denuded bone. I find two sinuses, which I cut into one and pass in my finger, pushing the tissues away with the handle of the knife. Now I find a portion of the crest of the tibia exposed and rough, while my director passes into a cavity in the bone. This is a condition not of necrosis, but of caries, and

it is necessary for you to make the distinction between these two conditions. If the bone were necrosed, it would offer resistance to my gouging efforts to remove it, but when it is carious I can easily chisel it away. When I cut and remove a piece of bone, it does not bring out a long piece with it as it would were it necrosed. This carious bone is in a condition analogous to that of the soft parts when in a condition of ulceration, it is more vascular than is necrosed bone; in other words, necrosed bone is dead, while carious bone is ulcerated. Now I bend my director, and it goes into another cavity, which I lay bare and gouge away further down, so as to give the carious portion an opportunity to be restored. There is considerable hemorrhage, as you see; this I will check by stuffing the wound with rags soaked in hot water. In the other knee there is slight flexion, but it is evident that the cartilages are not involved, and we need not interfere. Now, I have cleaned this ulcerated bone down to the medullary structure; we will pack it with hot water until the hemorrhage ceases, and then pack it with lint saturated with carbolic acid, and if there be much pain, envelop the limb in lead water and laudanum. I would neglect a very important point if I did not call your attention to the constitutional treatment; you might gouge away till doomsday and use all imaginable local treatment, but you would accomplish nothing without constitutional treatment. This boy has been taking iodide of iron and quinine and elixir of bark; also cod-liver oil and iodide of potassium. The latter was given as an alterative, if that means anything. Some of these patients have a decidedly scrofulous diathesis, though I have not been able in this case to detect any history of syphilis that would warrant me in saying that he has the taint; the teeth are notched, and the upper incisors are set towards each other, but there is no further evidence; there is no trouble with the eyes and no good reason for more than a mere suspicion, yet we will give him the iodide. Now, I want to contrast with this boy another one who has an acute synovitis of the knee; he has a perfectly good constitution, and no taint at all, as has the other. His father, with a queer idea of discipline, threw a beer-glass at his boy, and hit him on the knee; the moral effect may have been good, but the physical effect has been most disastrous. There has been a great deal of heat about the joint, and you will notice the difference in the outline of the limbs. Here in the sound knee is the patella, and on either side of it there is a depression into which I can readily press my fingers; now, on the injured side the patella is found floating up from the bones and it is a matter of difficulty to get into the hollows, and when I do I have the sense of displacing a liquid which is forced down among the tendons. From this I infer that there is an effusion of liquid into the joint. So also when this boy first came in, if I grasped the femur above and the leg below I could make considerable lateral motion, while in the normal joint there is very little lateral motion; this is due to the fact that the effusion separates the joint surfaces and the lateral ligaments are more or less relaxed. In this case we have no caries, as in the other, so that the treatment consisted in immobility, painting about the joint, above and below but not directly over the patella, with iodine, and constitutional treatment merely for the fever. Had it not yielded promptly, as it did, we would have resorted to extension.

Fracture of the Skull.

The next case that I will show is one of fracture of the skull, always of interest because of its medico-legal aspect. If a patient receives an injury to the head and remains insensible it is often a difficult matter to get an accurate history of the trouble and to arrive at a conclusion as to the nature of the injury. Even though consciousness may return, the memory may be so defective or the mind so confused as to offer the same obstacle. In this case, the old woman fell down stairs and struck the back of her head on a stone floor. The injury was received at a point just below the occipital ridge. Now, besides the medico-legal aspect of these cases, to which I have referred, a very important question arises as to the necessity and justification of the surgeon's interference. Now, as to depression. This injury is in a bad locality for trephining, yet if I had been sure that there was depression I would have considered trephining a justifiable and proper operation. The pupils were equal when she was brought to the hospital, though it was said that they had been unequal. There was some blood in the ear, but I think that it was from a lacerated wound of the scalp. I was so doubtful as to whether the sensation conveyed to the fingers was due to a depression of the skull or to an effusion of blood beneath the scalp, that I enlarged the wound and inspected the skull, when I found that there was neither depression nor displacement. That portion of the head was therefore shaved, a blister was applied, and

then an ice cap, and she was given half a grain of calomel thrice daily. Under this treatment she is doing well. She has not had that progressive increase of symptoms that are noted in fracture of the base of the skull. Such fractures are not always fatal, as I recently verified in a post-mortem examination of a man who had sustained such a fracture more than thirty years ago, but they are much more grave than fractures in any other locality. This effusion of blood under the scalp will all be absorbed. The night before last a man came into the hospital suffering from heart disease. The next day he threw himself head first from the window, striking on the brick pavement. He fractured his skull at two points, but there was no depression. He was picked up unconscious, his pupils were alike, and in a few hours he died. Through a large wound of the scalp we could detect a fracture, which, probably, extended around to the base, for here there was blood in the ear which we were able to satisfy ourselves did not come from the external wound, because, when we wiped it away, it was reproduced. Do not jump at conclusions; when after an injury to the head one finds blood in the ear, he is apt to conclude that there is a fracture of the base of the skull; but before reaching such a conclusion always be sure that the blood does not come from the external scalp wound. If you neglect this caution, you may get a reputation for inaccuracy, besides being misled in your practice. In this latter case, besides the blood, there was also serum in the ear, which was proof that there had been established communication between the ear and the cranio-spinal cavity.

Injury of the Hand from Machinery.

This girl was brought into the hospital the day before yesterday with her hand crushed from its being caught in machinery in a laundry. She did not desire to remain, wishing to go home as soon as it was dressed; but when we explained to her that we would not assume any responsibility for the future unless she staid in the hospital, she consented to remain. When she came in the hand was very much swollen, as was also the arm: I could not then feel the radial pulse. The arm was placed on a splint, and the whole dressed with lead water and laudunum. The swelling and inflammation has now much subsided, and in the course of the next twenty-four or forty-eight hours we will be able to tell the extent of the injury, which it is frequently quite impossible to do at the time of the accident. The question of the propriety of amputation always arises in these cases of extensive laceration, and it is not always easy to form a judicious opinion. You must always remember that the risk of tetanus in such cases is very great. It is quite possible that in this case tetanic symptoms may develop in the course of a few days, and if they did, my advice would be to amputate the moment the first symptoms manifested themselves. This is contrary to the teaching of many, but my opinion is based upon the experience of at least one case where tetanus developed after some days, and where I am satisfied that amputation was the means of saving life. This was a case where a finger had been torn away, leaving a jagged stump that was irritating the parts; the end of the bone was amputated, and the tetanic symptoms vanished.

Here is another case, in a man whose hand was caught in a cog-wheel; at first it looked very much as though amputation would be required, but on careful examination we decided to try to save the hand. There was a large wound, hemorrhage was free, and the metacarpal bone of the forefinger projected from the wound. The arm was placed on a splint, and the hand somewhat tilted backwards, so as to throw the metacarpal bone into place; sutures were used, and the whole enveloped in lead-water and laudanum. When sutures are used it is important to watch them to see that they do not produce too much tension; if they do, they must be removed. It was not necessary to ligate any vessels, for hot water checked the hemorrhage. Iodoform was used as a dressing, over which was placed antiseptic gauze. The limb was placed at rest, and he was given eight grains of quinine daily. He has done well, has had no fever, and the chances are that we will save the limb. The question will arise when there has been severe injury to the metacarpal bones, whether it is not best to remove the finger. I think it is, for the fibrous tissue that will take the place of these bones will render the finger practically useless, and I have never seen any good results from the effort to save it.

—Prof. Bonafoux, at a recent meeting of the Academy of Medicine, at Paris, read a paper upon a powder which possesses great hemostatic powers, and is capable, it is said, of arresting the bleeding of large arteries, so that it will prove serviceable in important surgical operations. The powder is prepared by mixing equal parts of colophony, carbon, and gum arabic.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

(*Concluded from page* 303.)

Dr. Trautmann: In one case under his care recently he found a well dilated os uteri and a free escape of waters; the pains ceased; ergot was given without any effect, and as the forceps were strenuously objected to, he was obliged to do nothing; after an interval of four weeks, labor came on naturally, and a living child was delivered. The unaccountable facts in this case are the widely dilated os, the escape of the waters, and a living child four weeks later.

Dr. W. S. Stewart: Sodium bromide is useful to prevent premature labor; five drachms may be divided into ten doses and one given every three hours. He has observed in one patient an apparent rupture of the membranes at five months, the fluid coming away with a constant drip; later, the flow was greatest at night; this condition lasted for six weeks, when it terminated in premature labor; the fœtus was living; the fluid which came away was examined and seemed to be amniotic. He also has observed retardation of labor from falling forward of the fœtus in relaxed abdomen. When such a patient is placed on her back, labor goes on rapidly.

Dr. Charles M. Wilson remarked that hydrorrhœa gravidarum is more frequent than is supposed, and is mistaken for premature discharge of amniotic fluid. Rigidity of the os uteri is most quickly relieved by inhalation of chloroform. He has found its action more satisfactory than that of chloral and sodium bromide or ether, and safer than morphia. Postural treatment of early stages of labor is of the greatest importance: he would place the patient on the floor on her knees or haunches; holding by the back of a chair or a post is often useful, as it assists in fixing the respiratory muscles. He has not had good results from the local use of belladonna.

Dr. Keating spoke of some experiments he had been making. The patient was first to practice Dr. Bonwill's method of inducing partial anæsthesia by rapid long breathing for a time, and then to hold the breath as long as possible. This method was found to bring on rapid and efficient pains in multiparæ with pendulous abdomens.

Dr. Baer remarked that, take it all in all, morphia, hypodermically, is the most valuable remedy we possess for the relief of pain and rigidity of the cervix during the first stage of labor. Of course it must be used within proper limits.

Dr. Richardson, in closing the discussion, said that his paper was not intended to be comprehensive. His use of morphia extended only to doses of $\frac{1}{6}$ of a grain every four hours, by the mouth, and not hypodermically. In the patient, whose history he had given, intermittent fever was developed later on, and he has not the slightest doubt of malarial poisoning being the cause of the untoward symptoms during and after labor; there was no fever, no rise of temperature, and therefore septicæmia is excluded. There can be no question as to the retraction of the cervix when the head is already in the pelvis; but when the head fits tightly into the superior strait and the cervix is jammed by it, the pressure upon the upper sac is greater than upon the lower, cut off from it by the head. Chloroform is more efficient than any other agent he had used, but it was not always to be preferred.

Dr. Keating exhibited a pair of scissors for denuding flat mucous surfaces; they were remarkably thin. He also exhibited a bivalve fenestrated speculum.

Vesico-Vaginal Fistula.

Dr. Keating reported the following case from notes by Dr. Howard H. Pardee:

Rebecca Johnson, colored, married, was admitted to the Philadelphia Hospital in the summer of 1884, complaining of inability to retain her urine, and of a constant bearing down pain in the hypogastric region, a burning pain in the bladder, and of frequent backaches. She had noticed that the urine was sometimes blood-stained in the inter-menstrual periods. She stated that about a year previously she had fallen out of bed, and had struck upon a broken chair, one of the rounds of which had entered her vagina, hurting her severely, and that all her symptoms had dated from that accident. Soon after her admission to the house an operation for vesico-vaginal fistula was performed by Dr. M. B. Musser, which relieved her for a time, but soon all the old symptoms returned. In January, 1885, examination revealed an opening from the vagina into the bladder more than an inch and a half in length, involving the neck of the bladder and the posterior part of the urethra: a pedunculated growth was also found in the bladder; this was removed. No history of venereal disease could be obtained; there was a bad leucorrhœa. In May, examination showed

an enormous vesico-vaginal fistula, the neck of the bladder and the urethra had entirely disappeared. The edges of the fistula were very thick and callous, and anteriorly very little tissue was left beneath the pubic arch. A small recto-vaginal fistula was also found, and exhibited the same thick rigid edges. Several deep scars were found on the nymphæ and labia majora, which seemed to be the marks of healed chancroids. An operation for the closure of the vesico-vaginal fistula was performed November 15, 1885, but the patient died a week later. The specimens, showing the wound closed, were exhibited to the society.

Dr. B. F. Baer presented the specimens and read the report of a case of

Hydro- and Pyo-Salpinx, Complicated with Follicular Degeneration of the Ovaries.

Mrs. H., æt. 42 years, was sent to me some months ago. She complained of great pain in both iliac regions, more in the right, radiating into the pelvis and sacrum and down the limbs. She had menorrhagia and profuse leucorrhœa during the inter-menstrual periods. She dated the trouble from an abortion which had occurred nine years before, and which was followed by symptoms of acute parametritis, from which she never fully recovered. Examination showed the uterus to be considerably hypertrophied and fixed as in a vise by an indurated mass on either side of it, which seemed to occupy both broad ligaments, or to be closely adherent to them. The cervix uteri was also badly lacerated, and its mucous membrane presented a surface so hypertrophied, abraded and jagged, that I was at first strongly impressed with the fear that epitheliomatous degeneration had begun to develop. I pursued a plan of treatment designed to reduce the congestion and hypertrophy of the diseased neck, and at the same time to induce an absorption of the plastic and indurated lymph around the uterus, to render the organ mobile, so that an operation might be made safe. I only partially succeeded, for, while the uterus became much more mobile, there still remained a swelling or tumor on either side of it. These tumors had ill-defined borders, were not circumscribed, but were elongated and rather cylindrical in form, and fixed to the lateral pelvic walls, as well as to the uterus, though not very firmly to either. I now suspected disease of the fallopian tubes, and probably also of the ovaries. The patient entered my private hospital in February, 1885, when I operated upon the cervix, dissecting away a large quantity of tissue for the purpose of making proper adjustment of the labia and to get rid of the cicatricial tissue. It was not epitheliomatous. I had hoped by this operation not only to restore the cervix to health, but at the same time to induce by a derivative action a retrograde metamorphosis in the diseased tissues and organs appended to the uterus. I succeeded in the former, and also in modifying all of the symptoms except the pain in the ovarian regions. This seemed to be made worse, or at least to become more prominent as the other symptoms were improved. The patient was sent to her home, and advised to rest in the recumbent position for at least a part of every day. Later, as she did not improve, a local treatment consisting of an application of the tincture of iodine to the fundus of the vagina at intervals of a week, with boroglyceride tampons almost daily. At the same time, counter-irritation applied to the iliac region by means of blistering was faithfully pursued. Nothing proved of more than temporary benefit. She began to lose flesh, and fail in strength. The fullness at the sides of the uterus had increased. She again entered my private hospital, and under anæsthesia I determined that the fallopian tubes were distended to the size of a small sausage, that the ovaries were also enlarged, and that the tubes, ovaries, and ligaments were all adherent to one another by plastic lymph; I advised laparatomy for the removal of the uterine appendages; the patient readily assented. A week later I made an incision three inches in length through the abdominal wall, fully two inches in thickness, and came upon the omentum, which was also very fat. This was adherent by its lower border to the pelvic tissues and organs, so that I was compelled to dissect it off on the right side before I could reach the uterus with my finger. Everything, fallopian tubes, ovaries, broad ligaments, uterus, omentum, and intestines, were so adherent and matted together that it was difficult to differentiate between them. The tubes were greatly distended, and contained, the right pus, and the left serum. The fimbriated extremities were glued to the lateral pelvic walls. The ovaries were as large as a good-sized hen's egg, and were closely adherent to the posterior surface of the broad ligaments. I dissected with my fingers, two being introduced until the right tube and ovary were released when they were drawn to the incision, ligated, and removed. The left tube and ovary were released with still greater difficulty, but I finally succeeded in ligating and removing them. Considerable hemorrhage occurred during

the operation, and it was necessary to place a number of ligatures. The abdominal wound was closed with eight silk sutures. The operation occupied more than two hours. The patient slept four hours before she returned to consciousness, and awoke without the slightest nausea, which both she and I dreaded very much from previous experience. There is not much to say concerning the after-treatment, for she did not require much. Her temperature never rose above 100°, and she made an uninterrupted recovery. She went home at the end of five weeks, and has been free from the old pain in the iliac region since four days after the operation.

Dr. B. F. Baer also exhibited a

Small Fibroid Tumor which had Undergone Calcareous Degeneration.

Mrs. L., æt. 60 years, a patient of Dr. J. H. Musser, of Lancaster county, Pa., has had two children and two miscarriages. She had been treated for uterine hemorrhage a number of times during the last fifteen years. She continued to "menstruate" until she was fifty-seven years of age. One year afterwards she began to suffer from severe uterine tenesmus, which was soon followed by a severe attack of "flooding." After this she had frequent recurrence of the hemorrhages up to the time of the removal of the cause. The case had been looked upon as one of cancer, and had been abandoned to the fate which attends that dread disease; but she lingered on and finally came under the care of Dr. Musser, who found on examination that the cervix at least was not cancerous. Through his kindness I saw the lady at her home in September, 1885. I must confess that when I entered the room I was almost on the point of quietly saying to the doctor that I believed his patient had cancer. She had a marked cachectic appearance, and there was an odor very like that of cancer. I advised that a thorough investigation be made with the patient under ether. I found the cervix smooth and soft, the os slightly patulous, and there were several mucous polypi hanging from it. There was also a fetid muco-purulent discharge which seemed to come from the cavity of the uterus. I removed the polypi and then carefully passed the sound into the uterine cavity. It was large and filled with numerous soft bodies, vegetations, except at one point at the fundus. Here a mass was detected which was as hard as marble, and gritty. I next dilated the cervix with my steel dilator, which was easily done, because the tissues were so soft and dilatable, and passed my finger into the cavity. The finger confirmed what the sound had led me to infer. I now removed with the dull curette all of the fungous vegetations—enough to fill a large spoon in the aggregate—and then again introduced my finger and found that the hard mass was imbedded in the uterine wall and pedunculated. I endeavored to remove it with my finger, but failed. I then pried it out of its nest with one blade of a polypus forceps. It proved to be a fibroid tumor which had undergone calcareous degeneration. I cauterized the entire surface of the uterine cavity with fuming nitric acid. The patient has had no hemorrhage since. The cure is valuable, scientifically, because it shows the fallacy and danger of neglecting cases of metrorrhagia—first, on the theory that the hemorrhage is due to the change of life, and therefore physiological, and second, on the supposition that because the hemorrhage came on so late in life, it must necessarily be the result of malignant disease and be permitted to run its course unmolested, Untold suffering and loss of life has resulted from this want of action. I have so recently expressed my views on this subject in a paper on "The Significance of Metrorrhagia Recurring About and After the Menopause," *American Journal Obstetrics*, May, 1884, that I refrain from further comment here.

Dr. Parvin remarked that in any case of uterine hemorrhage a careful examination should always be made. Hippocrates was the first to record the passage of stones from the vagina. From one patient under his care he removed forty tumors of this calcareous character. To illustrate the difficulty of arriving at a correct diagnosis, he related the case of a lady who had applied to him for the relief of an ovarian pain. She was elderly, and was the mother of three or four children. A year after he had first seen her the pain had left the ovary, and was then in the uterus; finally a needle was discharged spontaneously from the vagina, and the pain disappeared.

Dr. Chas. M. Wilson could not understand how Dr. Baer could make out the diagnosis in the case first described. With two inches of fat in the abdominal wall, how could slightly enlarged ovaries and tubes glued down by lymph deposits be detected? He felt sure he could not do it himself.

Dr. Parish said the diagnosis of such cases is at all times difficult, but the history of the case, with the aid of the examination. will make the diagnosis almost certain, sufficiently so to warrant an exploratory incision. Calcareous degeneration in fibroid uterine

tumors in old women is frequently found in post-mortem examinations. The calcareous mass may be as large as a child's head.

Dr. Baer, in closing the discussion, remarked that the great difficulty of making a diagnosis was an inducement to present the case before the Society. He had been eight months in making the diagnosis, and finally operated with hesitation and many misgivings. The pains were chiefly ovarian, but at first he contented himself with repairing the cervix and endeavoring to promote absorption of lymph deposits, and although there was improvement, the ovarian pain remained. When the patient returned, the cylindrical mass on the left side was two inches in diameter, and could be outlined per vaginam ; the ovary was as large as a hen's egg. "This I could determine by examination under ether; and on the right side a hard tumor could be felt. This proved to be the thick-walled tube filled with pus ; it was circumscribed, and attached to the broad ligament. I felt sure about the diagnosis, but the adhesions made me hesitate long before yielding to the desire of the patient for an operation."

W. H. H. Githens, *Secretary.*
2033 *Spruce street, Philadelphia, Pa.*

NEW YORK PATHOLOGICAL SOCIETY.

Anniversary meeting, January 13, 1886.
The President, John A. Wyeth, M. D., in the chair.

Periosteal Sarcoma of the Femur.

Dr. A. G. Gerster presented the lower portion of the right thigh, the seat of a periosteal sarcoma limited to the diaphysis, removed by amputation from a girl twenty-six years of age. Before the operation one surgeon who saw the patient thought the tumor a group of enlarged popliteal glands, and another thought it ecchondroma.

Myxo-sarcoma of the Testicle.

Dr. Gerster presented a myxo-sarcoma of the testicle the size of his fist, removed from a man thirty-two years of age. The causation was unknown. There was no history of injury or inflammation of the parts which would account for it.

Partially Descended Testicle, Fibroma, Hernia.

Dr. Gerster presented a specimen removed from a man thirty-three years old, who had noticed only one testicle in his scrotum, and who at the age of eighteen had a hernia, for which he was unable to wear a truss because of pain. In operating, Dr. Gerster came down upon the undescended atrophied testicle, a fibroma, and omentum adherent to the inguinal canal. The omentum was dissected up, deligated in several places, cut off, and replaced in the abdominal cavity ; the sac was transfixed with a catgut suture, tied like the string of a purse, the gut cut off, and placed in the inguinal canal. Finally, the pillars of the external abdominal ring were brought in contact, leaving a slit for the exit of the spermatic cord. The atrophied testicle was extirpated.

Dr. Gerster did not believe that operations for radical cure of hernia deserved that name. They might prove of benefit in enabling a patient to wear a truss.

Retention Cyst of the Submaxillary Gland.

Dr. Gerster presented the specimen, which he removed from a man aged twenty-six years. The tumor had previously been taken for a ranula. Tapped through the mouth, and collapsed; but it refilled, and became so large as to interfere seriously with deglutition, and even with breathing. Dr. Gerster removed it, and found it to be a retention cyst of the submaxillary gland developed toward the median line, and thus giving the impression of a dermoid cyst. The facial and lingual arteries were ligated during the operation.

The President had operated twenty times for so-called radical cure of hernia, and could not say with certainty that he had cured more than one case.

Fibroma of the Right Vocal Cord Removed by Mackenzie's Forceps.

Dr. C. H. Knight presented the specimen, which had for two years been the cause of hoarseness and dry cough. The pedicle was short. Hydrate of cocaine was employed during the operation. Six days later the voice was normal.

Congenital Absence of the Left Kidney.

Dr. T. Mitchell Prudden presented the specimen, which was removed from the body of a man twenty-two years of age, who had given no symptoms of renal disease, and who died of phthisis pulmonalis and tubercular meningitis. On the left side the supra-renal gland was in about its normal position, and was somewhat broader than usual. The left kidney and ureter were absent, there being not even a rudimentary trace of those parts. There was no left renal artery. The right kidney was moderately enlarged. The right ureter was slightly wider than normal. There were no other malformations in the body. Microscopically, the right kidney

was normal in structure. The case seemed to him worthy of presentation, not only because it was an excellent example of this form of malformation, but because, owing to the greater frequency of the operation of removal of the kidney in late years, a more exact statistical knowledge of the frequency of this malformation was for obvious reasons desirable. Up to 1883, according to Gootmann, there were within twenty-five years about seventy cases recorded in which one kidney was entirely absent or represented by a mere rudiment.

Dr. W. M. Carpenter said that about three years ago he saw at the post-mortem rooms of the Bellevue Hospital at least as many as three cases of single kidney, one being, if his memory served him correctly, an operation case in which the sole kidney was removed. Dr. Welch had made an autopsy on the body of a late surgeon of this city, and found but one kidney. Dr. Carpenter had seen no case since.

The President, some years ago, had occasion to study the abdominal viscera at a great many autopsies at Bellevue Hospital, but had never seen one case of congenital absence of the kidney.

Dr. W. P. Northrup said that in a thousand autopsies on babies he had not seen one case of absence of a kidney.

Dr. Gerster said that about the first operation which he performed in this country was for imperforate anus in a baby. He came upon something which appeared to be the intestine, but urine escaped through the incision. The child died, and autopsy showed that the much enlarged occluded ureter of an only kidney had been punctured.

Supernumerary Mamma.

Dr. A. Jacobi presented in behalf of a candidate a supernumerary mamma removed by operation from the left axilla of a woman twenty-seven years of age, who first noticed the tumor about the fifth month of her third pregnancy. The tumor had no connection with the left breast, and had no nipple of its own. Some milk escaped from the axillary tissue during the removal of the supernumerary mamma. After the operation, a small tumor of the left mamma disappeared spontaneously. The patient had feared carcinoma, as a relative had died of that disease. She was thin, and had not a very large breast.

General Tuberculosis.

Dr. L. E. Holt presented specimens from a child four months old, dead of general tuberculosis and a small amount of pneumonic consolidation. The specimen was chiefly of interest in connection with the history.

Diphtheritic Croup.

Dr. W. P. Northrop presented portion of the lung of a child which showed unusual extent of the croupous membrane, reaching to within half an inch of the base of the lung. The following was a cursory summary of 61 recorded cases of children dead of laryngeal diphtheritis or membranous croup at the New York Foundling Asylum, showing the extent of the pseudo-membrane: extending from the pharynx to the finest bronchi, 22 cases; from the pharynx to the bifurcation of the trachea, 9; from the larynx to the first division of the bronchi, 21; to the second division, 5; to the fourth, 3; over the pharynx and trachea, 2. Croup was the first symptom in 49 cases; membrane in the pharynx the first symptom in 12 cases; pneumonia occurred in 44 cases.

Dr. Northrop also presented Dr. O'Dwyre's perfected tube used in the asylum for the relief of dyspnœa by insertion through the glottis.

At the executive session, Dr. Wyeth was re-elected President, and Dr. Carpenter Secretary.

Editorial Department.

Periscope.

The Treatment of Pelvic Abscesses in Women.

Dr. Paul F. Mundé thus concludes a paper in the *American Journal of Obstetrics* for February:

1. Pelvic abscess in the female is not very common, in proportion to the great frequency of pelvic exudations, and probably does not occur in more than ten per cent. of all cases, the majority of exudations terminating in spontaneous absorption.

2. Pelvic abscess may be either extra-peritoneal, the result of cellulitis (by far the most common variety), or intra-peritoneal, the consequence of pelvic peritonitis. If intra-peritoneal, the adhesive inflammation be-

tween pelvic viscera and intestines may so seal the abscess cavity as to render it *practically extra*-peritoneal.

Abscess of the ovary and pyo-salphinx do not belong in the catagory of "pelvic abscess" proper, and do not fall under the same therapeutic rules, unless when, by agglutination to the abnominal wall or to Douglas's pouch, they become virtually extra-peritoneal.

3. Small deep-seated pelvic abscess, not exceeding a capacity of two ounces, and minute multiple abscesses in the cellular tissue, can often be permanently cured by evacuating the pus thoroughly with the aspirator. The surrounding exudation is then rapidly absorbed.

4. About one-half of the abscesses open spontaneously into the vagina, rectum, bladder, or through the abdominal wall and ischiatic fossa. These cases may gradually recover without treatment, or the sinuses may persist until closed by surgical interference.

5. Abscesses containing more than two ounces of pus should be opened by free incision along an exploring needle or grooved director, cleared of débris by finger or blunt curette, and drained and irrigated, if necessary, through a drainage tube.

6. This incision should be made at the spot where the pus points most distinctly, which is usually the vaginal vault.

7. In a certain number of cases the pus points through the abdominal wall, generally in the iliac fossa, and the incision should then be ample, and free drainage should be secured.

8. When the pus has burrowed deep into the pelvic cavity, and a probe can be passed from the abdominal incision down to the vaginal roof, mere abdomino-cutaneous drainage will not suffice, and a counter-opening must be made in the vagina, and a drainage tube carried through from the abdominal wound into the vagina. This drainage tube may have to be worn for months. In making this incision, care should be taken not to wound the bladder.

9. The opening of a pelvic abscess which points through the abdominal wall does not differ from, and is no more dangerous than, the same operation elsewhere on the cutaneous surface of the body. It is not an "abdominal section" or a "laparotomy," in the sense that these terms are now used to indicate the surgical opening of the peritoneal cavity.

10. Chronic pelvic abscesses, which have burst spontaneously, and have discharged though the vagina, rectum, or elsewhere for months or years, are exceedingly difficult to cure. This is particularly the case when the opening is high up the rectum. A counter-opening in the vagina, or enlarging the opening if there situated, the curette, stimulant irrigation, etc., may occasionally succeed, but usually fail.

11. A perityphlitic abscess may point through the abdominal wall, and simulate a pelvic abscess proper. Aspiration will settle the diagnosis; the treatment is the same.

12. The majority of cases of pelvic abscess recover; at least the mortality is small.

Gonorrhœa Treated Germicidally.

Dr. R. W. Barton thus writes in the *Miss. Valley Med. Mo.* for February:

Many microscopists agree that an organism of extreme minuteness is found in the discharge from the urethra of gonorrhœal patients, although there is a difference of opinion concerning its individuality and its etiological relation to the disease under consideration.

Neisser, in 1878, described a large micrococcus which he claims as peculiar to this disease, distinguishing it from ordinary cocci by its size, by the distance between the individuals in the groups—about equal to the diameter of a coccus—and by their occurrence upon the surfaces of cells. He considered it was the means of diagnosticating gonorrhœal discharges, although he failed to produce the disease by inoculating with the micrococci.

Bockhardt injected a fluid containing micrococci of a fourth cultivation into the urethra of a general paralytic, and was successful in producing a purulent discharge.

Dr. Geo. M. Sternberg, U. S. Army (*Medical News*, October 18, 1884), referring to a series of experiments, a detailed account of which was published in the *Philadelphia Medical News*, January, 1882, says: "The writer gave an account of a series of experiments, undertaken for the purpose of determining the etiological import of the micrococcus, which his own observations, and those of numerous other observers, had demonstrated constantly present in the pus of specific urethritis." Yet in his auto-inoculations with this micrococcus, as well as in two other healthy urethras, he failed to reproduce the disease.

Some bacteriologists, prominent among whom is Dr. Sternberg, deny that this micrococcus possesses any distinctive morphological charater, as claimed by Neisser and others.

Ogsten stated that he had detected their presence in pus from an ordinary abscess; and Dr. Sternberg, in a postscript to the article above referred to, confirms this observation.

While it would be gratifying from a theoretical standpoint to have determined, by a successful inoculation with the cultivated germ, that this micrococcus is the essential element of gonorrhœal contagion; still, as practitioners, we will only have to deal with cases resulting from inoculation with the gonorrhœal discharge itself. Notwithstanding the doubtful relation, in the minds of pathologists, of this micrococcus to gonorrhœa, the clinical experience of the writer and others would seem to afford valuable evidence of the bacterial origin of the disease.

With this principle as a foundation, the writer has, during the past eighteen months, treated some forty cases of the disease with creosote, administered internally, and employed topically in suppositories. Thirty-nine of these cases were in males, and one in a female; thirty-six were acute, and four were chronic cases. The creosote was administered internally in two-drop doses three times a day, employing any suitable emulsion, as mucilage acaciæ, or aromatic syrups, as a vehicle. Topically, the remedy was employed in suppositories, as recommended by Dr. J. H. Leslie:

℞.	Iodoformi,	grs. x.
	Morph. sulph.,	grs. v.
	Creosote,	♏ x.
	Butyri cocoa,	grs. xxx.

M.—Fiat supposit. urethral No. x.

S.—Insert one into the urethra three times a day.

These suppositories were particularly serviceable in two of the chronic cases; less so in two others, on account of disobedience of orders given. Dr. Leslie has, in his practice, employed creosote during the past five years, and considers its germicidal virtue as the curative property.

When I first employed creasote as a remedy, in 1884, I was not aware that the drug had previously been employed in this disease. Recently I have learned that Jonathan Hutchinson was one of the first to employ it; and Dr. R. Dichs, of Glasgow, recommended its internal employment in chronic gonorrhœa and gleet.

A consideration of the therapeutical action of creosote will recall that it is a general sedative and a local anæsthetic. Internally, its local effect on the urethra is coincident with its elimination by the kidneys. As physiologically and therapeutically creosote and carbolic acid may be considered alike (Roberts Bartholow), the one may be substituted for the other successfully in the disease herein under consideration.

Stunning and Burn by an Electric Lamp.

George Buchanan thus writes in the *Lancet*, February 13:

Injuries from electric lamps are becoming not infrequent. In most of the cases related death has been instantaneous. In a case reported on January 22 as occurring at Liverpool, the man was stunned and remained unconscious for a time, and on recovering was found to be quite blind. The case here related is very curious as to its causation and its effects.

William C., aged 44, a workman in Clydebank building-yard, was engaged at a crane on November 19, 1885. At the extremity of the wooden arm of the crane was an iron pulley, over which hung an endless chain for raising weights. The man had occasion to pull at the chain, and while so doing an electric lamp, which was suspended above, by some mischance was lowered till it touched the iron pulley. The lamp was one of the arc kind, worked on the Brush system. The instant this occurred the man felt a shock pass through him, became "doubled up," and then lost consciousness; but he did not fall to the ground, being held up by the chain which his hands firmly and involuntarily grasped. Some three or four minutes elapsed before the electric current was cut off at the machine, when the man dropped down on the ground stunned. He was taken to the Western Infirmary about an hour afterwards, by which time he had recovered consciousness, and could give a distinct account of what had happened. The injuries received were not very severe. There was a vesication of the palm of his hand where it held the chain; also one on the side of his neck, which rested against the chain during his pulling it down. On the sole of his right foot in front, where the chief weight of his body rested in the act of pulling, was a spot about two inches square, where the tissues were completely charred by the heat of the current passing into the ground. There were no nails in the boots, and there was no perceptible evidence of heat on them, but the sole of the stocking was charred opposite the charred part of the foot. Sir William Thomson, who questioned the man after his recovery, explained that the moist foot of the stocking must have acted as the medium of conduction between

the man's body and the ground, and so determined the seat of the burn.

The symptoms complained of were not very severe; they consisted of a slight amount of general shock, a feeling of heat in the abdomen and chest, and dimness of vision, all of which passed off in twenty-four hours. The wounds were treated in the ordinary way. A large slough separated from the sole of the foot, followed by rapid granulation and cicatrization, and the man was dismissed cured in about six weeks.

Sir Wm. Thomson suggests that if any of the bystanders had taken the man by the clothes and drawn his feet from contact with the ground, or had thrust a bit of dry clothing of any kind under his feet, the contact would have been broken, and the hand relieved from its grasp of the chain. The wonder is that an electric current powerful enough to char the thick integument of the sole of the foot, passing through the man, did not produce any internal mischief.

Dry Dressing for Internal Cavities.

Dr. Charles F. Hutchinson, thus writes in the *Lancet:*

Dry dressings being now all the fashion, and to my mind most justly so, I wish to draw the attention of the profession to a very simple method of applying, in the dry state, dressings, styptics, etc., to such cavities as the vagina, uterus, and rectum.

The only apparatus required is a hollow cacao butter suppository, which suppositories are made in various sizes, the largest of which will just about hold one drachm of any ordinary powder. These hollow suppositories are filled with the powder that may be wished to be used as a dressing; the small lid, after being gently heated, is put on; this when cool remains fixed, and the whole apparatus is then ready to be introduced into the vagina or rectum. The heat of the body soon melts the cacao butter, and the powder is then brought, in as dry a state as possible, into direct contact with the parts. During the last six months I have used these suppositories most freely, and have been more than satisfied with the result. I have tried all sorts of powders, and as the result of my own experience strongly recommend the following, either alone or in various combinations, as required.

First, as a styptic I most strongly recommend powdered iron-alum. I generally order one drachm of powdered iron-alum and five grains of iodoform, to be well mixed together, the powder to be inserted into a hollow suppository and used as directed. In the treatment of uterine hemorrhage I am convinced there is no remedy of more universal application, and none on which I could with greater confidence rely. I have used it in severe hemorrhage from uterine fibroid, from uterine polypus, from uterine cancer, bad miscarriage, and in several cases of menorrhagia at the change of life, and it has never yet failed me. All that is required is to introduce the suppository as high as possible into the vagina, and there leave it. It is as easily applied by the nurse as by the doctor, and is in every way perfectly safe and harmless.

Secondly, as a dressing iodoform stands pre-eminent; in fact, I now seldom use anything else. This, when combined with from a quarter to half a grain of morphia, forms by far the best dressing for uterine cancer that I have yet tried.

Thirdly, morphia, either alone, or, as I generally now use it, in combination with either or both of the above, is a great aid to the physician and comfort to the patient.

After attention has once been drawn to this simple mode of applying these various applications, the numerous uses to which they might be put in the various vaginal, uterine, and rectal discharges and diseases, will occur to all. I have only very briefly ventured to suggest the use of those which in my own hands I have found deserving of confidence. I have no doubt that hundreds of the profession are at present using this mode of dressing; but, on the other hand, I know that there are hundreds who are not, and it is to persuade those who have not yet tried them that I venture to bring this subject forward.

An Unusual Cause of Burns of the Face.

Dr. George T. Beatson thus writes in the *Brit. Med. Jour.*, February 13:

I have thought it right to put on record the following case, as it seems to me to be one of some rarity, and to have some importance from a medico-legal point of view. I cannot do better than give the facts in the words of the patient himself, who communicated them to me by letter. He writes as follows:

"A rather strange thing happened to myself about a week ago. For a month or so I was troubled very much with foul eructations. I had no pain, but the smell of the gas which came from my stomach was disagreeable to myself, and to all who happened to be in the room. About a week ago, as I

said, I got up in the morning, and lighted a match to see the time, and when I put the match near my mouth to blow it out, my breath caught fire, and gave a loud crack like the report of a pistol. It burnt my lips, and they are still a little sore. I got a terrible surprise, and so did my wife, for the report awakened her."

From the above occurrence, it would appear that the condition known as "halitosis," or diseased breath, is not only a source of misery to the sufferer and those compelled to associate with him, but may, under certain circumstances, become a condition of danger to the unfortunate possessor of it. In the present instance, the gaseous results of the imperfectly digested food had their atoms of carbon and hydrogen so arranged as to give rise to the presence of carburetted hydrogen, the inflammable and explosive qualities of which came into play when mixed with a due proportion of atmospheric air in presence of the unguarded light of the burning match. I may add, that the patient to whom this accident happened is a most intelligent and observant man, and that the diet I prescribed for the indigestion from which he suffers from time to time has alcohol excluded from it, and I know that my instructions in that respect are acted upon.

Meningeal and Cerebral Manifestations in Mumps.

As a contribution to the study of nervous disorders consecutive to acute diseases, the article by MM. Lannois and Lemoine in a recent number of the *Archives de Neurologie* deserves careful attention. The authors wish to demonstrate that the occurrence of aphasia and paralysis in the course of mumps is dependent on lesions of a grave nature of the brain itself. These serious lesions are not transitory, but last a certain length of time. Dr. Monro's case, published in the *Lancet*, August, 1883, is quoted. It was that of a boy, aged fifteen, who contracted mumps, and after apparently recovering was attacked with delirium, fever, and, one day later, orchitis. The fever increased to 106° on the fifth day; the pupils were dilated and insensitive to light, and there was marked constipation. The delirium increased and necessitated restraint. On the eighth day coma set in, and the pulse became almost imperceptible. Although the temperature abated slightly, still the patient had several maniacal attacks. At last he returned to complete health. But he had much difficulty in walking for six months, and also considerable trouble in speaking and writing. The pupils remained dilated, and the patient was highly emotional. In another case aphasia and localized paralysis of the right arm lasted for more than five days. The authors detail a case in which the aphasia and right hemiplegia lasted many months. It is their province to inquire into the nature of such cerebral disorders in mumps. Whilst admitting that hyperæmia or embolism might account for some of the cases, the hypothesis of a meningo-encephalitis is suggested. Generally this inflammation leads to nothing more than a superficial irritation, that rapidly passes away after having given rise to symptoms far more formidable in appearance than in reality. At other times, though fortunately of infrequent occurrence, the congestive stage is followed by encephalitis, which accounts for the long duration of the symptoms. The local removal of blood in cases of cerebral symptoms supervening in mumps, is regarded as sound treatment.

Anæsthetics.

Dr. R. Harvey Reed thus concludes a paper in the *Fort Wayne Jour. Med. Science* for January:

From this brief review of the anæsthetics most familiar to the profession, from a practical standpoint, we have arrived at the following conclusions:

1. Of all general anæsthetics known, pure sulphuric ether stands at the head, for safety, efficiency, and every day practical use.

2. Hydrochlorate of cocaine stands at the head of all known local anæsthetics.

3. Ethidene promises to rival ether, and merits a more general and extended trial.

4. No surgeon should give any anæsthetic without being prepared to resuscitate the patient on the shortest possible notice if necessary; among which preparations nitrite of amyl stands preëminent.

5. No person should be entrusted with the administration of any anæsthetic who is not thoroughly familiar with their physiological action and practical administration.

6. The indiscriminate use of anæsthetics should be strenuously guarded against; and especially the practice of leaving such dangerous compounds in the hands of the laity, to be given at liberty, whenever they may deem it necessary.

7. The judicious use of anæsthetics under all necessary circumstances should never be omitted; for when properly used by skilled hands they are a glorious haven of peace in the midst of a stormy sea.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

RESORCIN IN GONORRHŒA.

Dr. Andeer first recommended the use of resorcin in cases of gonorrhœa. Munnich, in Amsterdam, then treated 108 cases of the disease with 3 per cent. injections of resorcin, and published the very favorable results which he obtained from this treatment in the *Mon. f. prakt. Dermat.*, bd. iv., 6 June, 1885. His method is as follows:

The patients are recommended to drink much water and milk, so that the pus which has accumulated in the urethra may be thrown out with each discharge of urine, micturition always having to precede the injection. The injections are made by the patient himself, during daytime every two hours, and at least twice during the night; for experience soon showed that when the nightly injections were omitted the improvement obtained the previous day was lost again. It is further to be recommended that the patient do not retain the fluid injected into the urethra, but allow it to flow out again. Generally the fourth or fifth day the patients again presented themselves, when they were told to make the injections henceforth only three or four times daily, and but once during the night.

In 67 of the 108 cases the discharge had greatly diminished by the seventh day, and was totally cured on the fourteenth, and only in one single case the last small residue of the discharge had to be removed by a more astringent solution. In those cases which did not end so favorably, at least the acute symptoms rapidly yielded to the resorcin, and once the injections had to be omitted for a few days because an inflammation of the neck of the bladder had developed itself, in consequence of the patient's retaining the fluid too long in the urethra. All recent cases were cured within a fortnight.

Induced to do so by these favorable reports, Dr. Letzel, in his clinic for diseases of the skin and for syphilis in Munich, instituted a series of similar experiments. He tried the treatment with resorcin injections in 56 cases of gonorrhœa. Amongst these 33 were recent cases, none of which had lasted longer than a week, while the other 23 represented chronic cases, the most recent of which had a duration of two, the oldest one of five months.

In seven of 56 cases, 3 per cent. resorcin injections were not well borne, they causing severe pain; in two a painful priapismus set in, and in one the direct transfer of the urethral disease to the neck of the bladder was doubtless due to the irritating effect of the 3 per cent. solution of resorcin. The

other 49 cases evinced no trace of irritation. In consequence of this experience, L. later invariably commenced the treatment with a 2½ per cent. solution, and only gradually passed over to a 3 per cent. one. Thus all irritation was avoided, and in one very chronic case a 4 per cent. solution was finally also tolerated.

L. observes that the quality of the resorcin is of the utmost importance. The pure article is snow-white and easily soluble in pure water, while resorcin which has the slightest yellowish or brownish color only acts as an irritant to the urethral mucous membrane. The remedy further must be kept in perfectly hermetically sealed vessels; a larger quantity of the solution than four ounces ought never be prescribed, and this should be put into a dark bottle. Of the 33 acute cases L. was able to observe to their final cure 18 cases, and these gave the following results:

2	acute cases	were cured	within	7 days.
1	"	"	"	8 "
2	"	"	"	9 "
2	"	"	"	10 "
4	"	"	"	12 "
5	"	"	from 16 to	22 "

—while two of the eighteen cases, notwithstanding the early resorcin treatment, passed over into the chronic state. The average duration of sixteen cases was, therefore, twelve days. The other fifteen cases appeared only once or twice at the clinic; some of them were seen later, and reported "that the injections had done them a great deal of good, and that no trace of the disease remained."

The chronic cases of gonorrhœa did exceedingly well under a three to four per cent. solution. Ten cases, which had lasted from two and a half to five months, were all totally cured within from fourteen to thirty-two days by the resorcin injections alone, without the introduction of bougies.

All the cases reported by L. as cured were not pronounced as such until their morning urine evinced no longer gonorrhœal bacteria. L. does not doubt that with resorcin a great step has been made forwards in our treatment of this, proverbially, so often intractable complaint.

ILLEGAL PRACTITIONERS OF MEDICINE IN PHILADELPHIA.

It is probably known to the profession that we have a law in this State, as well as in very many other States, to regulate the practice of medicine; but it is in but few States that this law has been put into effect. In a few States efforts have been made at times to enforce it, but usually without much result—as a rule the sympathy of the jury being with the defendant, who was regarded as a persecuted man; this morbid sympathy usually arising from the fact that the intention of the law, and its enforcement, was construed as a selfish act on the part of the prosecutor, merely for the purpose of disposing of those who were receiving a portion of the money that the doctor wanted for himself. The true humanitarian principle involved, that of protecting the public from the harmful ministrations of incompetent and ignorant men and women, was entirely lost sight of in the erroneous impression that we have referred to.

There can be no doubt that there are to-day thousands of incompetent men in this country who are daily destroying life by ignorant treatment, and that such men should be stopped from their nefarious practices there can be no doubt.

About one year ago the Committee on Hygiene and the Relations of the Profession to the Public, of the Philadelphia County Medical Society, decided to inaugurate a warfare against these men. It was a task of no mean magnitude, owing to this very indifference and sympathy to which we have referred; but it was commenced with the assistance of able counsel in the person of Mr. Lincoln Eyre, a well known member of the Philadelphia bar.

The first case was the most difficult to contend with, but after a long delay, due to the slow-moving machinery of the law, the committee succeeded in securing the conviction of its first prisoner.

It now has two men under bail for trial, and proposes to go ahead vigorously until the host of these dangerous parasites that now infest the city are driven out, as were the rats from the plague-stricken city of Hamelin. One of the men now under bail is one of the most despicable specimens of adulterated manhood that we can well conceive of. With no qualification to practice, save that conferred by a limitless supply of pure impudence, he treated a respectable woman who had a scrofulous ulcer on her leg. Failing to secure from her all the money that his greedy demands required, he sent for her husband and told him that his wife had syphilis, and warned him that if he had anything to do with her while she was in this condition he would get the disease, and that it would eat into his stomach and eat him in two. When this poor man, who had no suspicion of his wife's fidelity, asked whether it was possible for her to have

contracted the disease in the privy or in some similar way, this wretch replied that such was impossible—that she could only have gotten it by having connection with some man who was very low, and who was rotten with syphilis. The husband left his wife and was gone from her for one week before he discovered the falsity of the tale he had been told. It is needless to say that the story was not true because even if it had been true it would be the duty of a conscientious physician to endeavor to hide such a misfortune.

In conclusion, we would ask the profession in this city to notify the assistant editor of this journal, who is the chairman of the committee, of any men who are illegally practicing medicine in their neighborhood.

Notes and Comments.

Comminuted Fracture of the Head of the Tibia.

Mr. William Thomson, of the Richmond Surgical Hospital, Dublin, has had reprinted from the *Transactions of the Academy of Medicine in Ireland* a case of that very rare form of fracture of the head of the tibia, which is produced by crushing, the force being the weight of the trunk and upper extremities, delivered through the condyles of the femur upon the articular surface of the tibia with such violence as to comminute it. This injury, which has received but very little notice in the best and most recent surgical writings, is not less destructive than that caused by some great external crushing violence applied directly, so as to break either the femur or tibia, or both bones, into fragments at their junction one with the other. To attain a fracture of the head of the tibia *par écrasement*, it is necessary, Mr. Thomson points out, that the person should fall from a sufficient height upon the feet, thus allowing the following weight of the body to come with great force upon the tibial head, when further downward progress is suddenly stopped by contact of the foot with the ground. The case reported by Mr. Thomson was one of compound fracture of the tibia, the lower fragment having pierced the skin at the junction of the upper and middle thirds of the leg. The patient, who weighed about sixteen stone, stated that he had been standing on a board supported between two ladders, when it toppled, and he fell to the ground on his feet, afterwards striking with his left leg the iron frame of a bedstead, which was close at hand. The patient died from blood-poisoning about a week after his admission, and, on post-mortem examination, two fractures through the shaft of the tibia were found, one about the junction of the lower and middle thirds, the other at the junction of the upper and middle thirds. The middle third of the bone lay as a loose fragment, and evidently its upper sharp end had acted as a wedge, and had split the head of the tibia into two principal fragments, the chief dividing line passing just to the left of the spine. On examining the upper articular surface, it was found that the left fragment comprised nearly the whole facet on that side, and was depressed about an eighth of an inch below the general surface. On the right side, the line of fracture began at the margin, about an inch from the central anterior point, passed obliquely backwards and to the left behind the spine, and terminated at the other fracture. Besides these fractures, there was considerable comminution of the head of the tibia, which was broken up into five fragments. The lines of fracture observed on the articular surface of the tibia were continued downwards into the head of the bone. This injury, Mr. Thomson states, is one of special interest, both because of the mode in which it was produced, and because of its character. Very little attention, it is thought, has hitherto been directed to injuries of the head of the tibia. This case is the tenth that has been recorded; but the injury, it is believed, occurs more frequently than is generally supposed.

A Rare Form of Dislocation of the Humerus.

The *London Medical Record* says:

A man, aged thirty-six, had his left humerus dislocated during a fray. He had been thrown to the ground, and, while he lay on his back, both arms had been pulled upwards by his opponent, a violent kick being at the same time given to the upper third of the humerus. When Dr. Lindén saw him, three days after the injury, the left arm was stretched upwards; the humerus formed an angle of about 130° with the acromion and clavicle; the forearm was pronated, and lay horizontally over the head, the left hand being supported by the right. The soft parts of the humerus were much contused. There was severe pain in the arm; the hand was numb, and was supported by the hand of the opposite side. All attempts to bring the humerus into the

horizontal position only caused severe pain. There seemed to be fracture of the humerus near the attachment of the deltoid, and on palpation the subacromial space was empty; on the other hand, the head of the humerus could be felt with unusual distinctness in the axilla. It lay below and somewhat to the inner side of the glenoid cavity, near the lower border of the pectoralis major. Under chloroform, the arm presented considerable resistance to attempts to bring it into the horizontal plane; it was, however, completely reduced by extension upwards and outwards. For six weeks the arm remained powerless; two and a half months afterwards it was still weak, but the man was able to work. Dr. Lindén has found only five cases of this rare form of dislocation recorded in medical literature. Two are described by Middeldorpf (*Schmidt's Jahrbücher*, 1880); one by Busch (*Archiv für Klinische Chirurgie*, Band iv.); one by Nikolaysen (*Norsk Magazin for Lœgevidensskaben*, 1873); and one, occurring in Bardeleben's clinic, by Alberti (*Deutsche Zeitschr. für Chir.*, Band xx.). In all these cases, the dislocation was produced by the arm being forcibly struck upwards. In one of Middeldorpf's cases, the injury was the result of a fall through a floor; in Busch's case, of a fall down a ladder while the patient was carrying a heavy burden on his shoulder. In Middeldorpf's other case, the arm was violently struck upwards by a windlass during a fall. In Nikolaysen's patient, the humerus was dislocated while he was trying, with his arm extended upwards, to prevent a boat from slipping off a vessel. In Alberti's case, a man was endeavoring to pull down a rearing horse by the bridle, when the animal struck his uplifted arm with one of its forefeet. In all these cases, the symptoms were similar to those above described. Dr. Lindén believes that the difficulty in reduction in his case was caused by the greater tuberosity of the humerus resting against the edge of the joint.

Respiratory Croaking of Babies.

The *Practitioner*, December, 1885, tells us that Dr. Samuel Gee has seen about a dozen cases of what he calls respiratory croaking in babies, and thus describes the affection: Breathing is accompanied by a croaking noise, which seemed to Dr. Gee to have the characters of stertor more than of stridor; or, in other words, the sound seemed to be produced in the fauces, and not in the larynx. The croaking usually accompanies inspiration only, but in one of the cases it accompanied expiration only. The noise is constant, both when the child is awake and when she is asleep; yet it may cease for a short time now and then. The tone of the cry is natural, and this is another reason for believing the noise not to be laryngeal. No dyspnœa, no recession of chest wall during inspiration. Fauces look natural. The noise continues when the nose is pinched. The croaking has nothing whatever to do with the crowing of laryngismus stridulus; the two disorders resemble each other in no respect, except that there is a noise produced in each. The ages of Dr. Gee's patients ranged from three to nine months. It is a remarkable fact that all of them were girls. The general health of some of the children was good, but most of them were weak and sickly. Two children suffered from congenital disease of the heart, and one was an idiot. In some of the children this croaking began at or soon after birth, and in no case did it last much beyond the end of the first year. There is no special treatment; indeed, the disorder causes more annoyance to others than to the child herself. Joseph Frank, in his "Praxis Medica" (De Morbis Laryngis, cap. ii., sect. 11), refers to observations of Storch which somewhat resemble these. But most of Storch's patients were older than Dr. Gee's, and he seems to have confused all kinds of stertor and stridor together. There is a much better description of the disorder in Rilliet and Barthez' book, "Des Maladies des Enfants," under the name of "Trachéite de la Première Enfance," but Dr. Gee's description, he says in conclusion, is wholly upon facts within his own experience.

Neuropathic Œdema.

We find occasionally local œdematous conditions in cases of myelitis and of tabes. They are often pronounced indications of an existing kidney complication, and are not seldom looked upon as important factors for the prognosis. Drs. Mathieu and Veit have made a special study of the subject, and come to the conclusion that these œdemas are no evidences whatever of diffused kidney diseases, but simply trophic disturbances, due to an alteration in the nutrition of the skin and the subcutaneous tissues. They found that these swellings frequently select the places which previously were the seats of lancinating pains, joints that had been painful were later similarly affected, and the swellings extended exactly over the regions

supplied by the painful nerves. In acute articular rheumatism similar œdematous swellings occur. Here also no form of Bright's disease need be present, which was absent in all the cases of myelitis and tabes observed by M. and V. They probably depend upon vaso-motor disturbances. While repeated analyses of the urine can alone determine the question in each individual case, the peculiar seat of the œdema—in the thigh or the upper arm, or around one joint, or surrounding two joints on the same side—does generally indicate their true nature, for in Bright's disease either the ankles and the parts of the leg near them or the tissues surrounding the eyes become first affected with œdema in diffused kidney disease. Besides, these swellings in morbus Brightii are never one-sided; they are apt, when not extensive, to disappear while the patient is in the recumbent position, and get worse towards night, after the patient has been much on his feet.

Poisonous Effect of Oil of Sassafras.

The *Deutsch-Amerik. Apoth. Zeit.*, (Oct. 1, '85) reports the case of an individual that swallowed two mouthfuls of oil of sassafras. A few moments later a cold sweat broke out all over the body, the skin became cold and pale, profuse perspiration then set in, and the patient lost consciousness. The pulse was threadlike and very rapid. Stimulants applied externally to the most sensitive parts of the integument, and emetics, caused a return of consciousness; but a general debility and a peculiar lassitude, which affected mainly the lower extremities, remained for some time after.

From the description of the case we do not believe that the oil of sassafras is any more poisonous than most of those strongly-scenting oils, for all of them, when taken in large quantities, are apt to produce phenomena akin to those of a severe attack of indigestion. Immediately preceding the vomiting, a cold sweat usually breaks out, while the skin becomes cold and the pulse thin and rapid. Very sensitive individuals easily faint in such an attack, and after the seizure is over the same general weakness is always observed. There is, therefore, nothing specially poisonous in the oil of sassafras, and in smaller doses it can be administered with perfect safety. Its effect is a stimulating one, with a tendency to increase the normal functions of the skin; and in this respect it greatly resembles the action of alcohol, which, when taken in too large a dose, also gives rise to the group of symptoms above enumerated.

The Relationship of Diseases of the Eye to those of the Nasal Passages.

Dr. H. F. Hendrix thus concludes an article in the *St. Louis Medical and Surgical Journal* for January:

To my mind there is nothing more reasonable than the relationship of diseases of the eye and nose. Anatomists have demonstrated the fact that the eye resides upon the same floor with the nose. I may say, therefore, that it is not strange that any deleterious matter brought into the house should, by continuity, spread to all parts of the floor.

The eye, as we see, is not the only neighbor which suffers from pharyngo-nasal catarrh. The ear is also connected through the Eustachian tube with the mucous membrane of the nose; hence we may expect the sense of hearing to be affected also. Now, when a patient comes to us suffering from a sore eye, let us examine the nose. If he complains of any ear trouble, let us examine the nose; if of a throat disease, let us examine the nose. With treatment properly directed to the mucous membrane of the nose and pharyngo-nasal space, we often cure the eye, the ear, and the throat, simply by striking at the root of the disease.

Bichloride of Mercury and Urea for Syphilis.

The *Pharm. Zeitung.*, No. 33, says:

Amide compounds of fatty acids with mercuric oxides, such as glycocol-, asparagin-, alanin-mercury, have been heretofore already proposed as antisyphilitic remedies (by Dr. A. Wolff). Recently another has been added to these by Dr. Jos. Schütz, which is not only inexpensive, but has the further advantage of not causing any pain. This compound is bichloride of mercury and urea. Schütz at first used a solution containing 1 gm. of corrosive sublimate and 0.22 gm. of urea in 100 gm. of water, corresponding to the molecular proportions:

$$\underset{270.92}{HgCl_2} + \underset{60}{CH_4N_2O} = 1 : 0.22$$

But since urea is usually a little damp, or contains traces of impurities, and a solution containing an excess of bichloride causes pain, a slight excess of urea is of advantage, particularly as it does no harm. Hence 0.5 gm. of urea were employed instead of 0.22.

It is not necessary to prepare this solution every day fresh, as it will keep for at least a week, and perhaps longer.

Scutellaria Lateriflora in the Treatment of Enuresis.

Dr. A. H. Wimermark, of Cambridge, Ill., thus writes to the *Medical Record:*

"Having read the excellent article on enuresis, by Dr. Stein, and the remarks of Dr. Willeford upon its treatment by rhus aromatica, I wish to contribute from my store of experience in the treatment of the same difficulty. Some two years ago I was advised by an old practitioner to use fluid extract of skull-cap in a case in my own family, and the result was most gratifying. I have since employed it in several cases dependent upon nervous conditions only, and must say that results obtained have always been most satisfactory. A lad, twelve years of age, who would urinate from three to six times every night during his sleep, and had done so for several years, received ʒj. t. i. d. for two weeks, and was speedily and permanently cured. All the cases occurred in children."

Dr. Wimermark advises a trial, at least, of scutellaria when other remedies have failed. He disclaims any credit for originality in the use of the drug, as he says that it was recommended to him by another.

A New Hypnotic.

Recently the MEDICAL AND SURGICAL REPORTER published the investigations regarding the effect of hopin, an alkaloid obtained from hops. It was first discovered in our country, and is mainly contained in American hops. Hopin has proven itself a very valuable hypnotic, more energetic and prompt in its action than morphia, and more free from all deleterious side-effects. Meanwhile, we read in the *Med. Blatt. of Jaksch.*, that another hypnotic has been discovered and been added to our therapeutics, viz., urethan, an æthyl ether of carbamin acid ($NH_2C\ O_2C_2H_5$). In doses of about 8 grains, taken from one to three times at night before retiring, it has a very prompt hypnotic effect, and not the slightest injurious influence upon the general health of the individual. In the urine of persons having taken three of the doses mentioned, no morbid product that could be ascribed to the action of urethan has been met with. Urethan forms white crystals, which are easily soluble in cold water, are completely without odor, and have a slightly salty and cooling taste.

Adulteration of Olive Oil.

Olive oil is frequently employed in medicine. To discover any adulteration, Andoynaud proposes in the *Compt. Rendues* the following procedure. Into a test-tube containing a ctm. scale, 2 cm. olive oil are poured, 0.1 grm. powdered bichromate of potash is added, and both are shaken without closing the tube. A mixture of sulphuric and nitric acid is next added until the fluid measures 4 ctm., and the mixture then stirred, when it will assume a red-brown tint. After one or two minutes ether enough is added to make the whole 5 ctm.; then the mixture is again stirred, when effervescence sets in. Red vapors escape, and if the oil be pure it floats with a green color on the surface, but should it contain only 5 per cent. of any of the cheaper oils, the color varies from greenish-yellow to yellow or even red-yellow, depending upon the quantity of the adulterating oil added.

Treatment of Sick Stomach after Ether.

Dr. Hearn, in the *College and Clinical Record*, says that the sick stomach which often follows the administration of ether, is annoying. It is difficult to do much for its relief. The patient may rinse the mouth with hot water, and if he can swallow some of it and vomit, he will get rid of considerable ether. The following is sometimes of service:—

℞.	Spirit. chloroformi,	gtt. viij
	Aceti opii,	gtt. iij
	Mucilaginis acaciæ,	
	Aquæ, āā	q.s.—M.

This may be repeated every two or three hours.

A sick stomach may often be prevented by administering a hypodermic of morphia before the patient comes out of the ether. It induces sleep until the effects of the ether have entirely passed off.

Breech Presentation Complicated by a Large Scrotum.

To the Buffalo Obstetrical Society (Sept. 22) Dr. Thomas Lothrop reported a case where he found some difficulty in differentiating the presentation. The examining finger first met quite a bag, though the bag of waters had previously broken; going a little higher it met on one side a hard bone, and, passing to the other side, another one. Soon it passed into what proved to be the anus, but there was no meconium. He finally decided that the bag was the scrotum, and very soon the penis came down, confirming that opinion. He mentioned the case as an example of some of the puzzling little features of obstetric cases.

"Dover's Solution" and "Red Drops."

A preparation, known as Liquor Doveri, Dover's solution (liquor ipecacuanhæ et morphinæ), which originated with Dr. J. D. Coleman, of Juliustown, and afterwards of Trenton, N. J., and is quite popular in several localities, is prepared as follows:

℞.	Acetate of morphine,	60 grains.
	Diluted acetic acid,	1 fl. oz.
	Dilute Alcohol,	7 fl. oz.
	Wine of ipecac.,	2 fl. oz.

Dissolve the acetate of morphine in the acid, add the diluted alcohol and wine of ipecac, and mix the whole thoroughly. Set aside for 24 hours, then filter through paper.

Correspondence.

Ligating the Cord.

Eds. Med. and Surg. Reporter:

In your number of January 30, 1886, appears a communication under the caption, "Ligating the Umbilical Cord," by Charles McIlvaine, in which he endeavors to present your readers with something new, the conception of which, it appears, took place during his short sojourn among the negroes on the Atlantic sea islands in the early part of our late war.

In his labor throes he has given birth to that which is indeed remarkable and unique. He says: "In every instance, when I asked the mother the age of her baby, and I had hundreds of occasions to do so, the invariable reply was, 'Why, bress de Lord, massa, de nable string been tied dis six weeks,' or whatever the number of weeks the child had been born, in cabin or cotton row, depending much upon the accidental whereabouts of the mother at the event."

Now, I was born and raised on the Sea Islands, and there practiced ten (10) years, largely among the negroes; have had, I suppose, equally as many occasions for inquiry of mothers as to the ages of their babies as your correspondent had, and never in a single instance did I receive such a reply as he states was invariably given him, nor did I ever hear the expression before. I can safely say that such a mode of computing the ages of their children is not customary among them.

Again, the expression "in cabin or cotton row" is well calculated to leave the impression on the mind of the reader that labor among the negroes was as likely to occur in the cotton row as in the cabin, thus charging, by implication, their owners with cruelty and negligence, whereas the truth of the matter is in direct opposition to such an accusation. When nearing the time of labor, the women were not required to leave the premises, but were employed at some light work thereabouts. A midwife was kept on hand, and in difficult labors the services of a physician were procured. No such instance as a negro woman giving birth in a cotton row or field, has ever come to my knowledge. That premature labors and miscarriages may occur while in the field I would not deny, although I cannot now recall such a case.

He says further, "The reckoning of the child's age was kept in this way—from the tying a knot in the umbilical cord as close up to the body as possible. The effect of this was visible upon every naked youngster, and quite noticeable in after life; the navel, instead of being depressed, protruded."

I have been in attendance on quite a number of accouchements among that class, and have examined their infants attended by midwives, and have yet to see a cord treated in the manner above described. Umbilical hernias are more frequent among the colored than the white children, but not so universal, and not caused by the peculiar treatment of the cord, as the writer would have us believe, but by different agencies altogether, which will occur to any reflecting physician.

A Bullet in Her Brain.

Eds. Med. and Surg. Reporter;

Noticing the ease reported by Dr. Miller in your issue of 26th of December, 1885, of the child "living with a bullet in her brain," led me to report the following somewhat similar case that occurred in the practice of a neighboring physician.

In March, 1876, a twelve-year-old girl was shot with a Sharp's four-shooter fired at a distance of two or three feet from her head; the ball entered one inch above and about three-fourths of an inch to the left of a line from the outer angle of the right eye. After receiving the shot the girl was unconscious about four hours; the left side was completely paaalyzed. A probe was passed fully five inches in the track of the ball, and brain matter to a considerable amount passed from the wound. With careful watching and judicious treatment by her attendants, the wound finally healed over, and the patient seemed well, excepting the paralysis of the left side. Her condition at present may be seen in the following statement I have from her father at this writing:

"My daughter has almost recovered the use of her left side, has good use of the arm, but sometimes complains that it is not as strong as the other. She goes slightly lame, and rather slides her left foot. She can do anything in general housekeeping, and her management of household affairs shows that her mind is not impaired. During the past ten years she has passed through several attacks of fevers, some quite severe, without any more difficulty than the other children. She went to school, and learned as well as she did before she was wounded. She has had no fits of any kind, and gives no other evidences of disability than the sliding of left foot and accompanying lameness, and the weakness of the left arm. The right side never showed any signs of weakness or paralysis. The pulse-beats can be seen and felt at the place of the entrance of the ball."

There is no doubt that this young woman has carried a bullet in the right side of her head during the past ten years, and that she is now apparently healthy, excepting as above stated. All the functions of her body seem well performed, her general condition good, and mind clear.

John W. Sheets, M. D.

Northumberland, Pa., Feb. 27, 1886.

Rare Symptoms in Hemiplegia.

Eds. Med. and Surg. Reporter:

Recently, in two cases of hemiplegia, the one right and the other left, I have noticed two symptoms which, among a large number of cases which have come under my observation during the last forty years, are quite new to me.

In the one, with no anæsthesia, and yet a complete loss of motion of both extremities of the right side, the patient could not be prevailed upon to allow sufficient heat in his room for the comfort of his nurses with overcoats and furs on, saying, "It is too hot here. I am burning up now." At this time, mercury without stood at zero. This complaint of heat continued for more than sixty days, when it was followed by the opposite sensation—cold. So severely did he complain of cold that the nurses were now as uncomfortable from heat as they had been from cold.

About this time there was a slight ability to use the lower extremity, yet there has never been any use of the arm.

In the other and more recent case, as well as, apparently, much milder, there is no anæsthesia proper, neither is there any complaint as to temperature, yet the patient when *himself* taking hold of the slightly affected hand (he being able to grip mine with considerable force), *with his eyes closed*, frequently asks, "Fred (one of his sons), have you got hold of my hand?" being unable to know that he himself has hold of it.

In the first case we very naturally say, "Oh, that is perverted nervous sensation;" but I cannot account for the patient's conduct in the second. I know the patient's ideas are perverted, but what perverts them in the latter case? Possibly Brown-Sequard might tell us.

Emission of Semen as a Means of Diagnosis of Death by Hanging.

Eds. Med. and Surg. Reporter:

I see in Medical and Surgical Reporter of 13th inst., among a synopsis of some of the papers read at the late meeting of New York Medical Society, one by Dr. Hamlin, of Auburn, on "Emission of Semen as a Means of Diagnosis of Death by Hanging." Having had opportunity of verifying Dr. Hamlin's observations, I report what I saw here in this city. There are hung in this city, annually, a dozen or more criminals, and in every instance there has been emission. The late Dr. J. E. Bennett called my attention to it in 1880, and my observations extend from that to the present. Dr. Bennett, who was United States jail physician at that time and many years previously, informed me that he never knew of a case of hanging in which the emission was not present, and as a means of diagnosis of death it was certain.

Fort Smith, Ark.

Quinine in Typhoid Fever.

Eds. Med. and Surg. Reporter:

I have read with much interest in your journal and in the *American Practitioner*, Dr. O. T. Shultz's method of treating typhoid fever, by giving large doses of quinine—ten, fifteen, up to thirty grains to control pyrexia—and from my experience with it, cannot recommend it, especially in this northern climate, where we have no malarial complications or influences. I have treated twenty-four cases of that disease within the last four months, running from the abortive form to the worst forms. I tried large doses of quinine in two cases (two brothers), and both died, and every other case got well. Whether the quinine aided the fatal issue or not is hard to say, but it looks suspicious, to say

the least. The largest dose was xx grains. Those treated with iodine and carbolic acid did well. Those treated with a sponge bath, quinine two grains every four hours, and a morphine powder at night, did as well as any. I would like to hear the experience of others in this direction.

News and Miscellany.

Medical Risks from Infectious Diseases.

Commenting on this subject, the *Lancet* says: One of the most interesting features in Dr. Ogle's paper on "Mortality in the Medical Profession," recently read before the Royal Medical and Chirurgical Society, is the comparison between the mortality of medical men from the principal infectious diseases, with the average mortality from the same causes among all males. That the mortality in the medical profession from these diseases should show a marked excess can cause no surprise to those who consider the constant risk of infection to which it is exposed. Dr. Ogle's figures are, however, mainly interesting from the exceptional position held by small-pox among these diseases. The death-rate of medical men aged over twenty years from scarlet fever is nearly four times the average rate of all males of the same ages; the medical rate from typhus is more than twice, from diphtheria nearly four times, and from malarial fever nearly five times the average rates for males of similar ages. Medical men are also liable to a markedly excessive rate from enteric fever and from erysipelas. The death-rate of medical men from small-pox, however, is considerably less than a fifth of the rate among all males.

Dr. Ogle suggests the only possible explanation of this remarkable contrast between the relative incidence of these infectious diseases on medical practitioners when he attributes their low death-rate from small-pox to more general and better vaccination and revaccination; and their excessive death-rate from the other diseases to the fact that no prophylactic is known wherewith to counteract, as in the case of small-pox, their exceptional risks of infection. Dr. Glover, in the discussion which followed the reading of Dr. Ogle's paper, expressed disappointment that the profession did not show complete immunity from fatal small-pox, and it is well, therefore, to point out that the rate of 13 deaths of medical men from small-pox per 1,000,000 living implies that during the ten years 1873–83 only 2 deaths from this cause, out of 3,865 deaths from all causes, occurred in the profession in England and Wales, numbering about 15,000. There were in England and Wales during those ten years 19,377 deaths from small-pox, and it is fair to assume that one or more medical practitioners were brought into personal contact with each of these deceased persons. Bearing these facts in mind, the deaths of but 2 medical men from this disease during these ten years induces overpowering evidence both of the value of vaccination as a protection from small-pox, and of its general and effectual adoption by the profession.

Prophylaxis of Cancer.

The *National Druggist* tells us that Dr. Willard Parker, in his work on cancer, which we have already mentioned in a former issue, makes some very interesting remarks on the causes and prevention of cancer, which, if rightly appreciated and followed by the public, would, no doubt, tend to reduce the frequency of this disease. He shows that cancer is a disease appertaining to civilization, and that barbarous and savage nations are comparatively free from it. Race and habitation, heredity, and other influences, are shown to have little effect in producing this disease. The use of intoxicating drink is considered, and its influence in causing cancer is shown to be slight. Syphilis and other diseases, he concludes, have no direct influence, since it is impossible that any one can have escaped some of the ultimate effects of a disease which was so prevalent in the last three centuries.

The predisposing causes of cancer, in all probability, are in the habits of the patients themselves. Just as civilization is the cause of the strain that wrecks so many intellects, so it is also the cause of depressing the animal vitality of the individual, and brings in its train this dread disease. The main cause of this disease is "established wealth and a state of luxury. The appetite for eating meat and highly-seasoned food is indulged, and can be regularly and habitually indulged, only in a state of established civilization, with communities engaged in accumulating fortunes and vying with each other in sumptuous living." These conditions, together with habits of indolence and insufficient exercise, cause an accumulation of waste products in the system which predisposes to cancer. Then, an accidental bruise, or reversal of fortune with mental depression, or any other exciting cause, may develop cancer.

The lesson is obvious. People should stop worrying themselves about the fact that a relative had cancer, because it does not affect them. They should live more frugally and take plenty of exercise in the open air, and, in short, follow hygienic modes of living, and the danger of cancer is much more remote. The cure may be difficult, but prevention seems to be in the power of each individual.

The Sanitation of Naples.

It is only two years since the editor of the *Brit. Med. Jour.* gave a graphic account of the pollutions of soil, air, and water, which were converting Naples into a pest-house, and threatened to make it a focus of zymotic disease. Soon afterwards came the epidemic of cholera, which verified the most alarming warnings. A German correspondent gives now a graphic account of the great improvements which are about to be commenced at Naples, and which will completely renovate the city from a sanitary point of view. One large main thoroughfare will traverse the whole of the poor quarters, Porto, Pendino, Mercato, and Vicaria, while regular cross-streets will run at fixed intervals. Some sites considered to be too unhealthy will not be allowed to be occupied. For the large crowd of artisans, laborers, and their families who will be dislodged by these changes, new and healthy quarters will be found in the Arenaccia district, beyond the railway station. The entire drainage and sewer system in the lower part of the city will be remodelled, and will be made to discharge beyond the harbor. The dye-works and similar manufactories, the operations of which are calculated to pollute the water, will be required to remove beyond the city boundary. The State is contributing $20,000,000 to carry out these great works. When they have been finished, the Chiaja will, indeed, be one of the most delightful, as well as most wonderful, promenades in Europe; but the habits of the people require also reformation, and a sanitary crusade needs to be preached on the basis of that which societies such as the National Health Society have carried out here. In this propaganda, the medical men of Naples might well take an initiative and active part.

Methods of Oleomargarine Manufacture.

From the *National Druggist* we learn that the present manufacture of oleomargarine and the component parts of it are substantially as follows: A mass of animal fat is heated to a temperature of 120° to 125° F. Salt is sprinkled over the top of the mass, and assists in the purificatiou and settlement of it. The fat becomes an oil, and is allowed to settle, and the best of it, or the straight fat, comes to the top, while the poor fat goes to the bottom, and when taken out is exported to Europe for candle-making. The clear fat is taken off, and is placed in large boxes holding from 500 to 600 pounds. In these boxes the fat is allowed to stand until cool, and it meanwhile granulates. Then it is put into heavy duck bags and placed under hydraulic pressure of generally about fifty tons to the square inch, though it sometimes reaches seventy tons, and the oleo oil flows out, leaving a hard mass of stearine, which is extensively used as an ingredient of lard.

The oil is then mixed up with certain proportions of milk and genuine butter, the latter forming as high as thirty-three per cent. of the whole and as low as five per cent., as the case may be. It is then churned up precisely like genuine butter, and comes forth oleomargarine. Sometimes considerable suet is used instead of the straight animal fat. This is at present the best and cheapest way of making oleomargarine, and is said to be the one generally followed, and the long list of deleterious and injurious substances does not appear. Butterine is, practically, a compound of lard and butter.

The American Medical Association.

The organization of the next meeting of the American Medical Association, to be held in St. Louis, Mo., on May 4, 5, 6, and 7, is announced as follows:

Practice of Medicine, Materia Medica, and Physiology: Dr. J. T. Whittaker, Cincinnati, O., Chairman; Dr. B. L. Coleman, Lexington, Ky., Secretary.

Obstetrics and Diseases of Women and Children: Dr. S. C. Gordon, Portland, Me., Chairman; Dr. J. F. Y. Paine, Galveston, Texas, Secretary.

Surgery and Anatomy: Dr. Nicholas Senn, Milwaukee, Wis., Chairman; Dr. H. H. Mudd, St. Louis, Mo., Secretary.

State Medicine: Dr. John H. Rauch, Springfield, Ill., Chairman; Dr. F. E. Daniel, Austin, Texas, Secretary.

Ophthalmology, Otology, Laryngology: Dr. Eugene Smith, Detroit, Mich., Chairman; Dr. J. F. Fulton, St. Paul, Minn., Secretary.

Diseases of Children: Dr. W. D. Hag-

gard, Nashville, Tenn., Chairman; Dr. W. B. Lawrence, Batesville, Ark., Secretary.

Oral and Dental Surgery: Dr. John S. Marshall, Chicago, Ill., Chairman; Dr. A. E. Baldwin, Chicago, Ill., Secretary.

"A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the chairman of the Committee of Arrangements, at least one month before the meeting."—*By-Laws.*

Committee of Arrangements: Dr. Legrand Atwood, St. Louis, Mo., Chairman.

The Influence of Articles of Food on Digestion.

In the *Rundschau Leitmeritz* of October 29, 1885, is contained the following on the influence of articles of food on digestion, which was originally contributed by Dr. Ogáta to the Archives de Hygiene:

"Water, carbonated water, tea, and coffee, in moderate quantities, do not disturb digestion. Beer, wine, and liquors at first retard digestion very materially (until they themselves are absorbed), and, in the beer, the extractives exert this action as well as the alcohol, which is shown by the fact that beer retards digestion more than a quantity of wine containing an equal amount of alcohol. Sugar (cane and grape) retards digestion considerably. Kitchen salt promotes it. Whether it is of benefit for the organism that digestion should take place slowly, or whether this retardation of the digestion is harmful, can not yet be determined from the experiments made. The author appreciates the fact that it is not totally unobjectionable to argue from the effects of certain articles of food on dogs, as to the effect on human beings who have been accustomed, from early youth, to the use of these same articles.

Lip-Reading.

A paper on lip-reading, by Mr. William Van Praagh, appears in the first number of the *Quarterly Review of Deaf-Mute Education.* The great importance of lip-reading to our deaf children is felt by all workers for the deaf; yet, until now, lip-reading has not received so much attention as it ought to have had. Indeed, considering the subject of deaf-mute education historically, it is noteworthy how new in this country the subject is. It is not yet a hundred years since the first public institution for its promotion was established. At the beginning of this century that institution was the only one. Now, however, a very different condition of affairs has been arrived at; and we wish Mr. Van Praagh all success in the efforts he is making to ameliorate the condition of our deaf-mutes.

The Sewerage of New Orleans.

A Memphis exchange says that Dr. Joseph Holt, President of the State Board of Health of Louisiana, is circulating in pamphlet form a timely and very able paper entitled "The Sanitary Relief of New Orleans," read before the New Orleans Medical and Surgical Association at its October meeting, in which he urges the immediate construction of a sewer system, boldly asserting that "New Orleans, to be saved, must be drained and cleaned." Incidentally the doctor tells his readers that within the last thirty-four years, from 1852 to 1885 inclusive, there has been expended by the municipal authorities, under the account of "streets" and "drainage," the enormous sum of $13,565,984. What is there to show for it? Nothing. A nice commentary, truly, upon the intelligence and capacity of New Orleans' municipal government.

The Profession in Russia.

In Russia there are 74 members of the Medical Council and 48 members of the Veterinary Commission. The total number of members of the provincial and county medical councils is 281. The roll of the profession contains 33,400 names, and there are about 380 female practitioners. About 2100 persons have the right to practice veterinary surgery. There are some 500 dentists and "oculists." The number of pharmacists of various descriptions is about 2600.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED FEBRUARY 20, 1886.

Austin, H. W., surgeon. To proceed to Richford, Vermont, on special duty, February 8, 1886.

Urquhart, F. M., passed assistant surgeon. To proceed to Richmond, Virginia, for temporary duty, February 16, 1886.

Professional Etiquette.

A patient came to a surgical clinic at the Rush Medical College to obtain Dr. Gunn's opinion of an operation which had been performed by another surgeon—simply to get

his *opinion* about what had been done. Dr. Gunn put him out of the room at once, stating that it was not his place to criticise other surgeons.

Items.

—The municipal tax formerly imposed upon traveling salesmen in Savannah, Ga., has been abolished.

—The news is cabled from Paris that M. Pasteur believes that he can prevent or cure diphtheria by a process of inoculation.

—A case of death from cocaine applied to relieve the pain of a decayed tooth is reported by Prof. R. Ogden Doremus to the New York Medico-Legal Society.

—An exchange says that in the lottery of life the dentist is always drawing something. Yes; and as in all other lotteries, there is always something rotten in connection with his drawing.

—An English physician says he has met with no case of offensive urine (intestinal-vesical fistula excepted) that ten or twenty grains of boracic acid given every three hours would not cure.

—*Puck* says that a wise St. Louis physician cured a case of alcoholism by prescribing opium. He then cured the opium habit by giving cocaine. Now he is searching for a cure for the cocaine habit.

—Ethyl hypochlorite has lately been prepared by Sandmeyer. It is a yellow, mobile, and very volatile liquid. When exposed to direct sunlight it explodes violently, even if kept, by means of ice, at a temperature of 32° F.

—A Sunday-school teacher asked a little girl of her class if she had been baptized.

"Yes," said the little girl; "two times."

"Two times! Why, how could that be?"

"It didn't take the first time," said the little girl.

—Oliver Wendell Holmes, in his fanciful "Arrowhead Village," makes the resident doctor declare that theological students develop a third eyelid—the membrane common in birds—which serves to shut out all the light they do not want.

—Board of Health Officer.—"Mrs. McGinnis, I told you last month that the keeping of that pig up here was a nuisance, and that it would have to be abated."

Mrs. McG.—An' shure Oi've obeyed yer insthructions intirely. Oi've been a-batin' the poor baste with a club ever since th' occasion of your last visit.

—Dr. Richardson finds a scientific basis for saying that a cat has nine lives. If a cat and a dog are shut up together in a lethal chamber, the cat survives on an average three times as long, and sometimes nine times as long, as the dog.

—The largest pharmacy in Europe, says the Vienna *Med. Zeitung*, is at Moscow, and is that of Woldemar Ferrein, where about seventy or eighty assistants are employed, and seven hundred to eight hundred prescriptions are prepared daily.

—A crystalline body has been obtained in minute quantities from the rind of pomegranates, which, when placed upon the tongue, or other portions of the mucous membrane, appears to paralyze the local sensation, somewhat after the manner of cocaine.

—Mrs. Wm. D. Sloane, a daughter of the late Mr. Vanderbilt, is, in connection with her husband, to erect and permanently endow a large and fully equipped free maternity hospital in connection with the College of Physicians and Surgeons of New York city.

—Intra-venous injections of quinine at the onset of the algid period of pernicious malarial fever, are, according to the report of Dr. Rouvier, surgeon-in-chief of the French Navy, an almost certain abortive, not merely stopping the chill but absolutely curative of the disease.

—On Monday, February 1, at the London Hospital, Mr. Frederick Treves removed from a woman, aged thirty-five, the left kidney, together with both ovaries—the kidney for hydronephrosis, the ovaries for multilocular cystomata. The patient, we understand, is doing remarkably well.

—The annual report of Dr. Cyrus Edson, Chief of the Second Sanitary Division of New York City, shows that there were condemned and destroyed in the last calendar year 799,410 pounds of meat and fish, 212,000 pounds of fruit, 37,905 pounds of canned goods, 72,700 pounds of candy, and large quantities of other kinds of unwholesome food.

—"What is the matter?" asked an Austin doctor of a thin young man named Anderson Pye. "I think the climate of Austin does not agree with me — have great trouble breathing with my lungs." "You would have a great deal more trouble breathing without your lungs," responded the doctor, whereupon Anderson Pye got up and adjourned; and now he tells every one that the doctor does not understand his business.

SOLUBLE PILLS.

Advanced pharmacy has, of late years, bestowed much attention upon eliminating the objectionable features which pertained to Pills, but it is only since their manufacture has been undertaken in wholesale quantities by responsible and capable parties that they have been produced of their present excellent quality.

The conditions of a perfect Pill are:

1st. *Ingredients of the finest quality.*
2d. *All materials weighed with scrupulous exactness.*
3d. *The mass sufficiently consistent to mantain the globular form, and yet readily soluble in the stomach.*
4th. *A coating which will preserve the mass in good condition, cover all offensive smell or taste, and facilitate deglutition.*

Those which we offer are not new to the profession, and the continued favor which has been shown them is sufficient evidence that care has been bestowed upon their manufacture. As for the purity of the drugs entering into their composition, and the presence in full and exact quantity of every article required by the formula in each case, we can only give our assurance that no deviation from correctness in any particular is, or ever has been, permitted in their manufacture; and then invite the most critical examination and test either of analysis or of therapeutic effect.

They possess the advantage of a perfect coating, which is neither hard, bulky, opaque nor insoluble, but elastic, thin, transparent and readily soluble.

RIDGE'S FOOD

FOR INFANTS AND INVALIDS.

Cereal foods are regarded by some with disfavor, as diets for infants, especially by those who maintain the dictum of chemistry in the matter as conclusive. It is urged that as they usually contain a certain amount of unconverted starch, this ingredient, owing to the absence from a baby's saliva of the solvent "*ptyalin*," must cause indigestion and irritation in its passage through the stomach and intestines. Yet Bouchardat and Sandras have demonstrated that starch, given to animals in excess of what the saliva can act upon, has its corpuscles eroded, dissolved, and transformed into sugar, when it meets the pancreatic fluid in the duodenum. The inference is that the conversion of starch is not wholly dependent on the secretions of the buccal cavity, and that the presence of a limited quantity in an infant's food is not necessarily a source of disorder. Moreover, in dietetic questions the verdict of chemistry can only be received *cum grano salis*; and the final appeal is to practical experience; what might, could, would, or should be, under supposed conditions, loses much of its practical value, when we have easy access to what is.

The preëminent popularity of Ridge's Food has caused it to be singled out for special criticism and attack, and unsparing denunciations have been hurled at it by and on behalf of unsuccessful rivals, whose professed zeal for the welfare and protection of the innocent public would be really touching, if it did not employ the language of disappointment and defeat. Our appeal to the public for its patronage has rested on the excellence of our product; and its full justification is found at this time in an experience of thirty years, during which the sales of Ridge's Food, throughout Great Britain and her Colonies, as well as in every State in the Union, have steadily and largely increased.

Ridge's Food is made from carefully selected winter wheat which, having been reduced to an almost uniform fineness, is thoroughly cooked by a steam baking process. The nitrogenous and phosphatic elements, in which wheat is so rich, are carefully preserved, and a large proportion of the starch is converted into dextrine, while the residue undergoes a further change when the food is prepared, as directed, in the nursery, producing an article of diet at once abundantly nutritious and easily digested. Samples of the preparation will be found alittle sweet and slightly alkaline.

It is claimed for Ridge's Food that it is acceptable to the most irritable stomach of infant or invalid, when used (as sometimes it must be) without milk; and that then it is alone sufficiently nutritive to sustain life.

It is also ammrmed that the objections urged against the use of cereal foods in no way or degree apply to our preparation; that the consequences predicted as following such a diet for infants never occur where Ridges Food is used. So contrary, indeed, is the prediction to the results of experience, that an eminent firm of druggists in Chicago, who for many years have sold largely of our preparation write: "Its soothing and satisfying properties are so marked, as often to cause customers to inquire *it does not contain some opiate?*"

We shall be pleased to forward a sample of RIDGE'S FOOD to any physician not yet acquainted with it, who may favor us with their address, satisfied that, with a fair trial, we shall secure his commendation.

THE DISPOSAL OF SEWAGE AND THE PROTECTION OF STREAMS USED AS SOURCES OF WATER SUPPLY.

BY GEORGE E. WARING, JR.,

Of Newport, R. I.

(*Concluded from page* 329.)

Around the whole interior of the tank, near its top, there is a perforated brass pipe connected with the main water supply by a float-cock at the bottom of the tank. This sends a spray over the walls of the tank during about an hour, partly before the discharge is complete, and partly during the earlier filling of the tank. Its purpose is to wash down accumulations of slime which might in hot weather become offensive. This part of the apparatus is to be removed during the winter season.

The irrigation field proper is about 1,000 feet distant, and its upper side is twenty-seven and one-half feet lower than the outlet of the flush-tank. This field is separated from the hospital grounds by a public road and by Stony Creek. Its lowest side is nearest to the grounds, and its higher or further side is bounded by a mill-race a little above its highest level. The area of the field available for irrigation is about twelve acres. Lying to the north of it is a piece of waste land two or three acres in extent, which has been arranged for use as a relief area in emergencies. Along the upper side of the irrigation field bordering the mill-race, is a deep trench with sloping grassed sides, and with a planked water-way at the bottom, for catching and carrying away the infiltration or overflow of the mill-race. Immediately inside of this ditch is the main sewage carrier, which extends from one end of the field to the other, and has a fall of 1 to 600 from its highest point, which is in midway of the field. At this highest point there is a circular well, six feet in diameter and seven feet deep, measuring from the top of its wall, which is a little higher than the surface of the ground. The eight-inch discharge pipe delivers into the bottom of this well, which thus serves to check the velocity due to the rapid fall of the connecting sewer. At its top there are three semi-circular openings two feet wide and one foot deep. One opens into the north carrier and one into the south. The third opens into another carrier, which leads directly toward the middle of the field. Ordinarily, only one of these openings is used at a time, and one is sufficient to deliver the whole flow. The north and south carriers, the banks of which are lower toward the field than toward the mill-race, overflow with much uniformity, and deliver the sewage at the top of a well-graded inclined surface over which it runs until absorbed. In no case does the sewage run quite the whole distance across the field. Movable gates being set at one point or another, the whole tankful of sewage may be delivered at pleasure over any area of from two to four acres, according to the inclination of the surface, and its condition of saturation by rain, or its dryness.

The carrier which runs toward the centre of the field delivers into a level ditch which surrounds a level tract about 2 acres in area. This is crossed by a series of parallel ditches 3 feet wide and 2 feet deep, separated by

beds or banks 8 feet wide, These beds are to be used for the cultivation of vegetables, forage, osiers, or whatever may be thought most advantageous. They receive their sewage solely by lateral absorption.

This level tract constitutes a relief bed capable of receiving several tankfuls of sewage in succession, and resembling somewhat the "intermittent filtration" beds used in England.

The whole of the field outside of the level tract is now sowed with rye and grass, and is already well covered. It is intended to use it as grass land only, and with the relief that can at all times be afforded by the level tract, by the emergency field to the north, and by the truck-patch, it need never be overflooded, and the sewage may at any time be kept off from any part of it long enough for harvesting. Judging from the experience of similar fields in England, it will be necessary to crop it three or four times during the season.

A considerable element of the cost of the work was due to the very unfavorable character of the ground, which, like that of the whole neighborhood, is a very heavy, stony, argillaceous deposit, underlaid by a stratified limestone, sometimes at a depth of 2 feet or more, sometimes lower than it was necessary to excavate. A sort of swale ran through the field from end to end, the land being higher at the bank of the creek than here. It was crossed with ditches, largely occupied by a tussock swamp due to a heavy underlying stratum of clay, and its old fence rows and ditch rows were overgrown with willows and other trees.

The cost of the preparation of the land was not less than $8,000, including underdraining, grading, uprooting trees, etc.; that is to say, it cost this amount to put it into the condition of a reasonably well graded, cleared, and naturally well-drained field. That part of the cost would be avoided where land of proper character is available.

One item of the preparation consisted in the laying of over 20,000 feet of draining tile at a depth of from 5 to 8 feet, more than half of which required rock cutting from a few inches to 2 feet in depth. It should be said that the rock is so fractured that water easily finds its way down to the level of the tiles. The underdrains are generally 25 feet apart.

The surplus water of the soil was substantially all removed by the digging of the ditches, so that when the tiles had been laid and covered, during dry weather, they discharged a very small stream. It took a long time to get the stony filling of the underdraining ditches so compacted and solidified as to prevent the direct flow of water from the surface to the tiles. Even now, there are some voids which have not been detected and filled, and some water flows directly from the surface to the tiles during the application of sewage. It soon ceases, and the effluent is clear within half an hour after the tank ceases discharging. In a short time this difficulty will be corrected, and it will always be clear.

The above is a brief and rough description of the general arrangement of the work. Its operation, so far as observed, may be thus explained:

All of the water-closets in the wards are flushed out at intervals of four or five minutes with a copious discharge from automatic tanks. This flow runs directly to the new sewers, and is sufficient in amount to maintain, day and night, a constant cleansing flow. The water-closets in the administration buildings and officers' quarters are operated by hand. They are all in direct communication with the same sewers. So, also, are the urinals (automatically flushed) and the wash-sinks and baths of the whole establishment; also, the sinks in the various dining halls. Such of these as are not to be abandoned on the completion of the new refectory buildings have been provided with flush-pots, by which their wastes are held back until accumulated to the amount of six or seven gallons, and then they go forward, with a rush and in mass, to the sewers.

The whole series of kitchen sinks are connected with a similar apparatus, by which, as above stated, from fifty to one hundred gallons at a time are discharged into the sewers through a four-inch outlet. The laundry apparatus from time to time contributes its very copious flood to the volume of the sewage.

Probably, in no case does more than fifteen minutes elapse between the emptying of any vessel in the establishment and the arrival of its discharge at the flush-tank. Within certainly less than twelve hours, and often less than eight hours, the tank, becoming full, discharges the whole accumulation into the main outlet-sewer leading to the irrigation field. The stream, running out through one or other of the carriers leading from the well, overflows its banks and spreads over the land. This complete process may take two and a half hours, so that if we add together the extreme limits of time, we have less than fifteen hours between the discarding of waste matter and its application to the surface of the irrigation field.

It is safe to say that putrefaction exists nowhere, at any time, throughout the whole system, and there is never at any point the least suggestion of the putrid odor inseparable from common sewers and cesspools. The only element of the mass which, in its fresh condition, is malodorous, is the fecal matter; as this is distributed through and drowned by not less than 2,000 times its volume of water, it counts for nothing as a source of exhalation. The whole flow might be discharged on the lawn in front of the administration building without offence save to the eye.

A few small coprolites withstand the rough usage of the current and are carried on to the ground, but they are so few and so very far between as not to be noticeable. Whatever solid matter passing through the screen is lodged on the surface of the field is destroyed by natural processes everywhere active. In no case is the amount of such matter or the effect from it worth noticing.

The real filth of the sewage—its dissolved and finely divided suspended matters—is carried into the ground, is retained there, and is destroyed by oxidation, and, through the activity of bacteria, by nitrification. As filth, it cannot pass through the soil nor very far into it. If the products of its resolution are not consumed by plants, they pass off with the under-drainage, as soluble salts devoid of all organic character and unaccompanied by the lower forms of organic life.

After a few days' use of a single tract, the sewage is turned to another tract, and again to another and another, being allowed nowhere to run long enough for the closing of the ground against infiltration by clogging, or for the gorging of its interior spaces with impurities. In short, the process of purification is complete and continuous. Experience elsewhere indicates that the soil will in time improve in its purifying power from year to year for a long time.

There are larger examples of the purification of sewage by irrigation elsewhere in the world, and examples of which the lesson is enforced by long experience; there is, so far as I know, no example in existence more carefully arranged as to its details, involving the overcoming of greater natural difficulties, or better illustrating the more modern technical methods of the art.

I may be excused for suggesting that this example, so near to your own doors, points out the way in which the sewage of the towns now draining into your own water supply may practically, and without too great cost, withhold their filth from their drainage, making the Schuylkill once again a fit source from which to draw household water.

Another method of disposal by application to the land which is especially applicable to isolated houses, and to establishments when the discharge cannot be removed and must be concealed, is what is known as "sub-surface irrigation," a process invented by the Rev. Henry Moule, for use in connection with the earth-closet, and first applied systematically by Rogers Field, Esq., an English engineer, in connection with the drainage of some cottages at Shenfield, in Essex. Its use in England has never extended very much.

In this country its first application was in connection with my own house at Newport, in 1869. After ample experience and observation of its efficiency, I began to use it in my private practice as an engineer, in disposing of the sewage of isolated houses. In 1876 I had become so confident of its success that I applied it to the sewage of the whole village of Lenox, Mass. In 1879 it was applied on a still larger scale at the Woman's Prison, at Sherburne, Mass., and in 1881 to the hotel at Bryn Mawr. The details of this system have been very materially perfected, and its use is now common in many parts of the country, there being hundreds of examples in New England, and probably as many within a radius of ten miles about Orange, N. J. The Lenox work being the oldest of the larger ones and the one longest in use, may be taken as an illustration of the system generally.

Lenox was a scattering village with less than 1,000 persons living in reach of the sewers. The fund available for sewage was small, not enough to lay an outlet-sewer to the river, over two miles distant, to say nothing about work in the town. Indeed, a discharge into the river would not long have been tolerated. At that time (1876) much less was known than now as to the efficiency of sewage irrigation. As the most promising means for overcoming the difficulty, I decided on the adoption of sub-surface irrigation, using 10,000 feet of distribution pipes, underlying a well-graded area of about one and a half acres. The pipes were laid a little more than one foot below the surface. They were common 2-inch agricultural sole tiles, laid directly on the earth. They were divided into 20 lines, with as many connections with the main pipe leading from the flush-tank. The manner of connection was never very satisfactory, and the general arrangement was never entirely suc-

cessful from the point of view of an expert. However, although the field was but a few hundred feet distant from the village, there was never any serious complaint from it, and there was generally great satisfaction with it, although, as the flushtank had no settling basin for holding back solids—only a strainer—there was always more or less trouble from obstructions, and, as the population increased, these obstructions increased, until now the whole affair is in such condition that it seems necessary to reconstruct parts of the work in accordance with methods since universally adopted. At the same time, with all its drawbacks, it has been essentially successful and satisfactory, no nuisance having arisen from it that was perceptible at any distance from the field, and no attention having been called to it by reason of its condition. It has been quoted and visited, as an instance of a great advance in the disposal of the sewage of a village, and it only needs slight improvements to make it available for perfect work for years to come, provision being made for distribution over the surface of the field, at times, during the short period when the village is full of vistors.

At the Woman's Prison the system was much more correctly constructed and has been correspondingly more successful, though it is seriously overtaxed with an effluent of about 30,000 gallons per day; the more especially as the contributing pipes lie in a bed of muck and heavy silt, one of the least successful materials for this use.

At the Bryn Mawr Hotel the same system has always worked satisfactorily since it has been sufficiently extended to deal with the large volume of sewage; but, mechanically considered, this is not a test case, for all of the sewage is received and retained in large cesspools, the absorption drains taking care only of the putrid liquid discharged from them.

After large experience with this method of distribution, I should not hesitate to use it for a community of any size, if it were a mere question of mechanical arrangement and of purification. I should hesitate to use it except where the distribution ground is in the immediate vicinity of houses, simply because it is much more costly and much less simple than a discharge over the surface, which, as has been amply proven before and is amply proven now at Norristown, answers every requirement of simplicity, safety, and decency.

I cannot better close this paper than with extracts from a report made on the 25th day of July, 1885, to the Chamber of Deputies of France by M. Bourneville, a deputy, submitted in the name of the committee appointed to examine the proposed law having for its object the agricultural utilization of the sewage of Paris and the purification of the Seine.

I adhere as closely as possible to the original text, thinking that, as former statements about this work have been disputed, a close translation is more important than a freer rendering in English. M. Bourneville says:

"The vast experiment at Gennevilliers comes in its turn to confirm the great laws of natural purification and agricultural restitution, attested by the numerous examples that we have collated.

"It was in May, 1869, that is sixteen years ago, that the sewage first reached the land of the plain of Gennevilliers. There had already been for two years (1867 to 1869) several thousand cubic metres distributed by irrigation or treated by chemical reagents at Clichy on an experimental field, where the pumps now stand; a certain number of vegetable products had been obtained on about two-thirds of an acre. The experiment transported to the other side of the Seine, at the beginning of the plain of Gennevilliers, began in 1869 on six hectares (fifteen acres) bought by the city of Paris and retroceded by it to several well-disposed cultivators. The disasters of the war came and destroyed the first installations; they were put into condition again at the commencement of 1872, and since then the service has been regularly performed. On the 3d of June your commission visited in detail the pumping station of the city of Paris and the plain of Gennevilliers. We have gathered together, on the ground and in the documents placed at our disposal, the most circumstantial information on the results obtained."

The report then describes the character and arrangement of the pumps, connecting pipes, distribution pipes, etc., and continues:

"The volume of sewage sent into the plain of Gennevilliers, which was only 1,765,621 cubic meters in 1876, was 15,000,000 in 1880, and finally 22,493,992 cubic metres in 1884. From 1872 to 1885 there have been spread on the plain of Gennevilliers 157,000,000 cubic metres.

"The irrigated surface has undergone a corresponding development. Beginning with 57 hectares in 1872, it reached 121 hectares in 1874, 200 hectares in 1875, 450 hectares in 1880, and finally 616 hectares on the 1st of January, 1885. The sewage is

distributed over the tracts by about twenty laborers, each of whom is charged with the supply of from 25 to 30 hectares, and with the management of about 30 outlets. In view of the extreme division of property and the diversity of culture, the volume of sewage delivered into the plain is distributed so uniformly as to require no reservoir and no 'regulator;' simple standpipes placed near the steam pumps and at different points along the pipes regulate the pressure.

"During the season of active vegetation, the cultivators are present on the fields during nearly the whole day to the number of about 1500 men, women, and children; they lead the water into the ditches from the distribution outlets with a care and a skill which would leave nothing to be desired in the best irrigations of the south of France. During the three or four months of winter, vegetation is only partial; the laborers then interfere more directly; they cause the sewage to flow in the gutters and trenches in such a way as to insure purification by oxidizing action; the solid portions remain in the gutters and form a paste which the peasants afterward incorporate with the earth in the first plowing of spring. This is the case especially for cereals; the vegetable products utilize the winter deposits in the form of a top-dressing of the beds.

"At Paris, as at Berlin, this formation of the deposits and the irrigation continue during the greatest cold, sewage water having always a temperature of at least 5° or 6° (40° to 44° Fahr.). This was realized in the severe winter of 1879, and during the three weeks of continuous frost of last winter. During great floods of the Seine the pumps are generally stopped, leaving to its flow the removal of the entire discharge of the main sewers."

Then follows a table, showing that in 1884 the volume of sewage used in irrigating, per month, varied from 1,205,358 cubic metres in February, to 2,766,782 metres in July. The monthly average for the year was 1,874,491 cubic metres.

"At the time of the visit of your Committee, the volume delivered to the cultivators each day reached from 130,000 to 140,000 cubic metres for every twenty-four hours. More than one-half of the sewage of Paris was purified and utilized by the plain of Gennevilliers during the heated term and during low water of the Seine—that is to say, at the time when the discharge of sewage into the Seine is specially objectionable.

"The results obtained in the plain, from the point of view of cultivation, are most remarkable. Your commission traversed, during more than two hours, fields covered with products of the greatest variety and abundance; vegetables of all sorts, cereals, grass, and nurseries.

"They obtain generally 20,000 to 40,000 heads of cabbage per hectare, 60,000 heads of artichokes, 10,000 kilogrammes (over 100 tons) of feeding beets, and five or six cuts, yielding from 80 to 100 tons of green forage. The gross product obtained per hectare varies from 3,000 to 10,000 francs ($600 to $2,000) and even more for crops.

"It has been said, in the presence of the Commission, that the horticultural products of Gennevilliers were of bad quality. It has been written that *the vegetables produced by this soil, surcharged with infected water, are bad to the taste, and the forage offered to live stock is not nutritive, and is, besides, rejected by them.* On this point here is the opinion formulated in a special report to the Agricultural Society of France by Mr. Michelin."

Then follows a table showing that the 616 hectares were occupied for the growth of cabbage, artichokes, potatoes, asparagus, salads of various sorts, peas, carrots, beans, parsley, onions, beets, luzerne, grass, sundry vegetables, nursery stock, trees, and serials. Mr. Michelin says:

The Society has, through its committees, always observed the results obtained in the horticultural experiments which have shed light on this question, which we in the horticultural world of Paris regard as solved from the practical point of view, with reference to the beauty of the products, their quality as to taste, the success of the production, and the certainty of sale. In affirming the quality of the vegetables to be proper for the nutrition of men as well as of animals, it should be explained that the liquid ought not to be put in contact with those parts of the plant which are above ground, but only with their roots."

The Committee asserts that "all the vegetables of Gennevilliers are advantageously sold in the *Halles*, as well as in the markets of the environs. They carry off the first prizes at the horticultural exhibitions of Paris, and even of Seine-et-Oise. About 800 cows are fed with the aid of the irrigated grass and plants. The average dose of sewage used by a hectare, divided over the whole surface dedicated to irrigation, is about 40,000 cubic metres a year. It is really, if we include what is not used directly, about 50,000 cubic metres. Certain parcels, specially treated, under an arrangement with the cultivators and by way of experiment,

with high doses, have been receiving for three years 80,000 cubic metres by regular irrigation summer and winter. They are covered with a luxuriant vegetation.*

"The rental value of land, which was formerly from 90 to 150 francs a hectare, ($7.20 to $12 per acre)—we speak, of course, of the cultivated land—is now from 450 to 500 francs ($36 to $40 per acre) in all the irrigated area. As to the selling value, it is from 10,000 to 12,000 francs ($800 to $960 per acre). All leases now accepted by the cultivators carry the provision that the high rent is not consented to, except on the condition of sewage being disposable for the leased land.

"The commune of Gennevilliers asked and obtained, by the treaty of 1881, that for a period of twelve years the sewage should remain at the disposition of its inhabitants as freely as they should desire, whatever might be the projects and works of the city of Paris for the extension of irrigation (elsewhere).

"Irrigation with sewage has, therefore, brought wealth to Gennevilliers. Notwithstanding the evidence of these results, there is among the adversaries of the present project one who maintains that this wealth is an illusion, and that in reality the irrigation has caused to Gennevilliers an irreparable wrong, because no one seeks this locality for the construction of villas. The answer is simple; we take it from Mr. Francisque Sarcey: 'The population, which was not dense,' says he, 'cultivated more or less well a rebellious soil. They had only to scratch the ground to meet the sterile sand and the arid gravel. A few country houses had pushed in here and there around Gennevilliers itself; but it was by exception, *for the emigration of the Parisian Bourgeoisie in search of villas passed to one side and pushed generally further on.* Those who had stopped there could have been seduced only by the cheapness of the land. It seemed that this country, struck with a sort of malediction, was never to lift itself from this condition, when, in 1869, the sewer commission of Paris selected it as the theatre of an experiment which was to produce a happy change in its appearance.'

"The purity of the subsoil water, which receives all of the water filtering from the irrigated land, is perfect. M. Pasteur has testified to this with his high authority before the committee.

"All may judge of this, as your committee has done, by the examination and the tasting of the water that flows out of the five lines of drains 18 inches in diameter which surround the village of Gennevilliers, and discharge into the Seine about one kilometre from each other. These drains, having a total length of about eight kilometres (five miles) have been established at a depth of four metres (12 feet) at the normal level to which it was desired to reduce the subsoil water; in the case of floods, or of very heavy irrigation, these drains facilitate the outflow of the water and prevent the invasion of quarries and cellars.

"As M. Marie-Davy, Director of the Observatory of Montsouris, testified before the committee, the water of the drains is chemically pure. It contains barely 0.001 of a gramme of organic nitrogen to the cubic metre even at those points, as in the experimental basins of the gardens belonging to the city of Paris, where the annual or continuous dose reaches and passes 80,000 cubic metres per annum. With Liebig's boullion which shows 62 micro-germs in a cubic centimetre of water of the Vanne, 1410 for the Seine at Bercy, and 20,000 for the sewage, there are found only a dozen inoffensive micro-germs in the water of the drains, which thus sustains the opinion of M. Pasteur. At the same time, the large contents of chlorine, 0.07 of a gramme per litre, indicates the presence in the subsoil water of a large proportion of purified sewage which has passed through the ground.

"The sanitary condition of the commune of Gennevilliers leaves nothing to be desired; the Mayor and his Adjuncts, Doctors Thobois and Cornilleau, testified before the committee at its visit to Gennevilliers, and it is enough to walk about in the plain and see the vigor and good health of the hundreds of men, women, and children who are working eagerly (avec ardeur) in the midst of the irrigated fields, to understand the true state of the case. The *general mortality* in 1865 was 32 per 1,000. In 1876 and 1881 it was only 25 and 22. No epidemic of typhoid fever has existed for long years, although the irrigations were continued on a large scale during the cruel epidemic which attacked Paris in 1882. Not a single case of cholera occurred in 1884. Never from 1869 to this day, although the inhabitants eat their own vegetables, even uncooked, has there been observed a single case of *anthrax* or *septicæmia.* In fact, all of the information that we have gathered from most of the physicians who have had occasion to be called to Gennevilliers proves that intermit-

* At this rate, one acre would purify the sewage of over 500 persons, at 40 gallons per day.

tent fever shows itself very rarely, and that the number of cases does not exceed that of localities more or less remote, and of which the fields are not subjected to irrigation.

Still another argument pleads in favor of the excellent sanitary condition of Gennevilliers, that is, the increasing growth of population, as shown by the following table:

1st of January,	1869 . . .	2186	inhabitants.
" "	1872 . . .	2218	"
" "	1880 . . .	2389	"
" "	1885 . . .	3245	"

"Such are the facts that your committee has established in the plain of Gennevilliers; it has been constantly accompanied by the authorized representatives of the population of the plain and its suburbs: MM. Pommier, Mayor, and Retrou, Adjunct, of Gennevilliers, Berthou, Mayor of Saint Ouen, Hennape, Mayor of Puteaux, our friend M. Bailly,. Mayor of Courbevoie, Honorary Inspector-General of Public Assistance. A deputation of the culivators of the plain gave the committee all the information as to details that it needed. No discordance was developed; the unanimity was complete concerning the excellence of the results obtained and the absolute innocuity of the system. The majority of your commission cannot refrain from expressing to you the confidence that these demonstrations give it in proposing to you the continuation and extension of sewage irrigation."

The publication of this report must have been most gratifying to M. Durand-Claye, the champion and the wise and eager director of the work at Gennevilliers, who has fought its battles against prejudice, ignorance, and malice, from the days of its struggling infancy to this hour of its complete triumph, and his own.

At Gennevilliers, as at Croyden, Berlin, Dantzic, Breslau, and the Norristown Asylum, complete evidence is set before us of the absolute efficiency of the system of purification by application to the soil, which, it seems to me, on the score of economy and of completeness, as well as by reason of the conditions generally prevailing in this country, has such advantages over the best of the chemical systems that it is, in at least a very large majority of cases, better suited to our needs.

Nor can it be doubted that this system will enable us to restore and to maintain the purity of our water-courses, especially when these are used as the source of water for domestic use.

A CASE OF INTUSSUSCEPTION—RECOVERY.

BY H. G. CLIPPINGER, M. D.,

Of Pipestone, Michigan.

January 14, 1886, I was summoned to see Miss B., aged 10 years, living four miles out in the country; the messenger stating she had a bad diarrhœa, and was vomiting nearly all the time. Being busy, I sent some powders of sulph. morph., bis. subnit., and cretæ prep. arom., with directions and orders to report if it failed to control the trouble.

January 21. I was summoned again, the messenger stating the powders cured her before, but this time her sickness was different. I found the child with an expression of great suffering, saying her "belly ached so bad." Her temperature was 100°, tongue dry and red, pulse 99, abdomen distended and tender, and vomiting whenever she swallowed anything, and sometimes when quiet; bowels constipated. I could not detect a hernia. They gave her castor oil and some pills the evening before and during the night. I gave calomel, grs. vii., sodæ bicarb., grs. vii., dose to be repeated every three hours, and injections of soap-suds until bowels moved, and left opiates to quiet pain afterwards. Ten hours later symptoms worse. The nurse thought her bowels moved sufficiently. I was satisfied they only moved below the obstruction. Temperature 101°, pulse 110, abdomen tense and painful, irritability of stomach no better. I tried other purgatives per mouth and rectum with no success.

January 22. Symptoms growing worse, and vomiting a little stercoraceous matter. Used opiates hypodermically to quiet pain.

January 23. Growing weaker. I now renewed the calomel and soda, as it was about the only thing the stomach could not dislodge. I could not see her until the morning of January 24, when her expression and tongue looked a little better. Temperature 101°; pulse 120. Abdomen very much distended, with paroxysmal pain of a severe griping nature and constant tenderness. I continued treatment of previous day. In the evening countenance and tongue improved in appearance. Temperature 100°. Had three small passages of mucus from bowels during the afternoon, and a little gas escaped just before I entered the room. At 10 p. m. she had a small rectal passage in a fluid condition. These kept up from every half to one hour for three days. I stopped all purgative agents, and placed the patient upon powders of morph. sulph., bis. subnit. et cretæ prep. arom., with stimulants. During

the treatment I used emollient and sedative applications to the abdomen. The distention left with the movement of the bowels, but the paroxysmal pain and irritability of stomach remained; the stomach now began to retain a little nourishment for a little while.

January 27. In the morning her stools began to have a putrescent odor, which kept growing more offensive during the day. In the evening, four inches of the intestine passed away. No change in other symptoms.

January 28, at 4 a. m., 3½ inches more of the bowel passed in a partially decomposed state. Stools very offensive. At 10 p. m., a little over seven inches of bowel passed. This section of intestine was in a better state of preservation. After this the offensive odor ceased.

January 29. Found patient better. Stomach less irritable. Alvine evacuations less frequent. A little appetite. Temperature 98°. Pulse very feeble. From this time on the abdominal pain and tenderness gradually subsided, and three weeks later I dismissed the patient in a fair state of health.

There are a few questions I will ask the profession concerning this peculiar case. Did the calomel relieve the congestion of the stricture so as to permit a small amount of fluid to pass before the death of the bowel? And why should the bowel die three days afterward? Why did the intestine pass at different times, in different states of preservation? Would it be the physician's duty to perform laparotomy under the circumstances? Information through your valuable journal will be gladly received.

Hospital Reports.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of Dr. Roberts Bartholow.

Phthisis Pulmonalis.

The first case that I have to show you today, gentlemen, is interesting from the fact that it illustrates the form of phthisis pulmonalis that comes on after and is dependent upon pleuritis. A distinguished New York teacher has called our attention to the fact that there is a form of phthisis that follows pleuritis, that is due to an extension of the inflammation by continuity of tissue from the pleurisy to the tissue of the lung proper, resulting in a chronic inflammation and ultimate degeneration of the lung itself. Sir Andrew Clark, in England, who is Gladstone's physician, and is therefore the medical lion of the day in that country, has lately delivered some lectures on this subject, and illustrated his remarks with a large number of cases. There is a condition, so to speak, of chronic pleurisy, with a chronic fibroid condition of the lung, which persists until the bacilli are deposited, when it caseates, breaks up, and cavities are formed. Now this young man offers to us a typical case for observation. Eighteen months ago he was perfectly well. There is no tubercular history on either side. He was at this time seized with pleurisy, after which he had an abscess on the face, the scar from which you see. Now though there is no history of struma or tuberculosis in his family, you will observe that he himself offers the strumous diathesis very well marked. He had, he tells you, two attacks of pleuritis, after which he had cough and expectoration. The pleurisy was bilateral, and now both lungs are affected; please note this fact. I can distinctly elicit the cracked-pot sound, from which fact I know that there is a cavity near the middle of the right lung. There are general moist large and small rales over the whole aspect of both lungs; so that we have all the ordinary rational and physical signs of phthisis, for he is emaciated to the last degree. His temperature is now 101°, but I have no doubt that in the evening it goes up to 102° or 103°. Our experience here for some time past tends to confirm this idea that phthisis does originate from pleuritis, for within the past few weeks we have had several cases just like this one. The treatment, which must be supportive, I will not now dilate upon; you are familiar with it.

Probable Floating Spleen.

We have here a very interesting case for diagnosis. The man presents himself to us to find out what is the matter with him. When we look at him we see that he has a very much enlarged abdomen, but what is the cause? His countenance is good, he is a little pale, but on the whole he seems to be in fairly good condition. For about eighteen months past, he tells us, his abdomen has been progressively enlarging. He has not had much suffering, that is to say, that while he has experienced some uneasiness and discomfort from this swelling, it has never been sufficiently great to force him to resort to anodynes for its relief, Upon percussion, I find the abdomen flat nearly all

over its surface, save in the most prominent part in front, where, no doubt, the resonance I elicit is due to the floating upwards toward the surface of the intestines. Now, I am quite sure that there is fluid in the abdominal cavity, for I can plainly detect fluctuation. When I press my fingers deeply into the abdominal walls, I can feel a hard body, a tumor, between my thumb and finger, low down in the median line, between the symphisis pubis and the umbilicus. It is firm, somewhat sharp in its margins, and when I manipulate it carefully, I find that I can float it upwards, more especially in the direction of the left hypogastrium; therefore I know that this tumor, whatever it may be, is movable. Well, now, we sometimes find that the liver is movable. In all persons it is possessed of some slight mobility. When erect it slightly descends, and when recumbent it ascends again, but there are some few exceptional cases where it has very considerable latitude of motion, the ligaments, common duct and blood-vessels forming a pedicle that is sometimes quite long. So also may we have the kidney movable; indeed, such a condition is comparatively frequent, especially in women who have borne many children. So, too, the spleen is occasionally found free to move. I have examined a case where there was great ascites and a movable spleen, with a pedicle one foot long. Therefore we have three organs that may shift about and give us such a tumor as we have here. We have in the first place to consider that we have, as I have said, a hard body, which may be regarded as a tumor. Well, now, we might have an aneurism in this location, an aneurism of the mesenteric artery, but this tumor is not pulsating, and it is not in close contact with the aorta, else we would have the aortic impulse transmitted. So, then, I think we must narrow down the possibilities to the question of floating liver, spleen, or kidney. If we were to jump at a conclusion from the fact that we can most readily move the tumor up into the left hypogastrium, we would say that it was the spleen. But let us first look for the spleen in its normal position, and ascertain whether it is there wanting. This would seem easy to do, but it is altogether a different question to examine for this body when the abdomen is in its normal condition and when it is enormously distended, as in this case. There is so much fluid here that it would be impossible to accurately determine anything about so small a body as the spleen. Well, let us then look at the liver. Here we encounter the same difficulty as in the case of the spleen, but if the liver has been pushed up by the accumulation of fluid, we will find an increased area of dullness in the thorax. Now, on percussion I find dullness up near to the apex; so then I am inclined to think that the liver is in its normal position, save that it has been pushed up by the fluid. So now I have to come back to the spleen, Let us look into the shape of the tumor; it rather corresponds in outline to the shape of the liver; it is somewhat sharp in outline, and here I feel a notch, but remember that the spleen varies very much in shape, and we may have notches in that organ. Well, then, with all this doubt surrounding us, what can we do? There is only one thing to do, and that is to remove the fluid. We will tap this man, and when the abdomen has been thus reduced, we will be able to tell all about these organs.

Passage of Gall-Stones.

While we are waiting for the next patient I want to show you some interesting specimens, and say a few words about the passage of gall-stones. You will read in your books of certain symptoms set down as diagnostic of the passage of biliary calculi, and if you always wait for the appearance of such symptoms, you will be, not infrequently, most woefully disappointed. Now this stone which I show you is quite large; you see there is a nucleus of inspissated bile that is coated with crystals of cholesterine, outside of which again you observe a brown coat, which is the phosphate of lime and biliary coloring matter which has become added to it after it passed into the intestine. Well now, in this case, this large calculus was passed without the occurrence of any symptoms. This is a curious fact. that very often no symptoms will attend their passage. There is no colic and none of the usually described derangements. Their manner of discharge, too, is interesting, for it occurs that they ulcerate through into the intestines. But after they get into the intestines they often cause trouble, as happened here. For some time this woman complained of great uneasiness in the region of the cæcum; she had movable pain, shooting from the cæcum to the angle of the colon. The question of treatment became a matter of great doubt. The case occurred in Illinois, and many doctors were called in consultation, none of whom were able to arrive at a definite opinion as to the trouble, nor to formulate appropriate treatment. The only symptom to guide them was the presence of pain,

which might, of course, be due to many causes. Some considered it to be caused by flatulency, and many and diverse were the opinions formulated. Finally, one day, after taking a purgative, she passed this stone with a loud noise as it struck the chamber, which called attention to it, and it was recovered. Immediately thereafter, all symptoms disappeared. She was very fortunate to so get rid of it, for it will happen that such an obstruction will act as a nidus for the accumulation of fæces, and we will have intestinal obstruction from this cause. From this case I wish to draw, for your guidance, a very practical point. Remember how obscure may be the passage of biliary calculi, and in all cases where a patient passes small, hard, round fæces, save them and break them up or dissolve them, that you may see what they contain.

Mercurialismus.

This young man offers for our study a condition that you will not very frequently encounter. In order to get rid of some parasite, he bought some mercurial ointment and used it five times, and now he comes to us with all the symptoms of mercurial poisoning. Shortly after the last application he had fever, headache, nausea, and diarrhœa, followed by profuse salivation. Since then, his vital functions have been very much depressed, and his gums spongy. There has been no paralysis, but you see this eruption on his limbs which I would call a mercurial eczema. Here, then, we have the symptoms of acute mercurialismus. It is interesting to note how quickly the toxic condition followed a local use of the poison. He bought fifteen cents' worth of the ointment and used it all in five applications, in the course of two or three days. In such cases, changes may be produced in the spinal cord that will result in paralysis; he has had as yet no paralysis, but it may come on later. There is, you must know, a form of myelitis, due to mercury; therefore we must not consider that all danger has passed because the more acute symptoms have subsided, for he may yet have a series of paralytic troubles. As for treatment, the first and principal indication is to secure the elimination of the mercury, for it is wonderful to note how this poison will permeate the system. Some distance away from its point of introduction we may find the globules, for the metallic mercury will pass through the interstices of the tissue, while there will be also a process of oxidation, and it will be found as an albuminate. To eliminate the mercury we will use iodide of potassium, which is the best agent, as it forms, with mercury, a soluble salt that will be excreted by the kidneys. If the case is an obstinate one we should resort to sulphur baths, which are highly prized in this connection by the French. The skin and all the emunctories should also be kept active, but the most important indication is the administration of iodide of potassium.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, January 7, 1886. The President, B. F. Baer, M. D., in the chair.

Dr. Howard A. Kelly exhibited recent specimens of

Pyo-salpinx, Hydro-salpinx, and Papilloma of the Hilum, with Gelatinoid Thickening of the Fallopian Tube.

The histories of the cases will be given at some future time.

Dr. Goodell stated that while he recognizes the necessity for operation in pyo-salpinx, he does not think it necessary in hydro-salpinx. He now refuses to operate in some cases of cystic disease in which one ovary may contain a cyst as large as an orange, or in which the tube may be distended to the size of a sausage, because the sufferings of the patient and her general symptoms are not severe enough to warrant the operation. In many of these cases the symptoms may all be removed by the rest treatment, and it should first be tried. Small cysts are frequently found in ovaries, especially when uterine fibroids are present, but they do not necessarily develop into large ones. In many cases the cause of pelvic symptoms can be diagnosticated by exclusion only, and even when small cysts or dilated tubes can be felt, treatment should be first tried, and will be sometimes successful without operation. He thinks the error of the present time is in the direction of too much surgical interference.

Dr. Montgomery remarked that there was a class of cases suffering from small ovarian cysts or distended tubes, in which the rest treatment or any other loss of time could not be thought of, and in which operation seemed imperative. This was on account of the pecuniary condition of the patient, who may be self-supporting, or who may be the only support of others; the suffering and ex-

haustion of the disease incapacitate them for work; relief is imperatively demanded, and he considered operation justified.

Dr. Goodell recognized this element of poverty, and has operated for this reason in some instances. He was led to make his remarks by a case now under his care. A lady was sent to him for operation after an opinion had been given by an experienced gynecologist of another city that relief could be obtained by operation only. On one side the ovary was enlarged and the other ovary was prolapsed and tender. Rest treatment had wholly cured her. In these remarks he casts no reflection on any of Dr. Kelly's cases. Pus was present in all of them, and operation seemed to be demanded in all.

Dr. Baer has been strongly impressed lately with the views expressed this evening by Dr. Goodell. Dr. Baer thought all conservative means should be tried before operating.

Dr. Kelly replied that he had presented the specimens purely from an anatomical and pathological standpoint, and that he will give the histories at some future time when the results of operation are well demonstrated. In each of them operation was imperatively demanded to save life. It is in such cases as those presented this evening that the great work in the future must largely lie. If the details of ovariotomy have been perfected, in such cases as these the chapter is only being opened. They are not examples of Battey's operation, or Tait's operation, but stand as representatives of classes of disease well defined, with equally well defined indications for treatment. The extraordinary difficulty of digging such masses as these out of the pelvis makes the operative interference very fatal, although it is the only resort.

Dr. Willliam Goodell read a paper on "A Year's Work in Laparotomy," which will be published in full in the *Medical News*. During the past year he had had forty-four cases of laparotomy, with four deaths, as follows:

	Cases.	*Deaths.*	*Recovery.*
Ovariotomy	28	2	26
Oöphorectomy	9	1	8
Hysterectomy	2	1	1
Exploratory incision	4		4
Pelvic abscess	1		1
Totals	44	4	40

Of these forty-four cases, twenty-five had been operated on at his private hospital, with two deaths; twelve were operated on at the Hospital of the University of Pennsylvania, with one death; and seven were operated on at the homes of the patients, with one death. Of these four deaths, one only was due to septicæmia, and that, a case of oöphorectomy, occurred in a private room of the Hospital of the University. It was not, however, due to hospitalism, but to the adverse complications of the case. The ovary and oviduct were filled with pus, and so matted by inflammation to adjacent structures that only a portion of them could be removed, and that in fragments. The pus unavoidably escaped into the peritoneal cavity, which was carefully cleansed and a drainage-tube put in; yet a fatal inflammation set in. Another death was due to shock after the removal of the womb containing a fibroid tumor with extensive adhesions, and weighing seventeen pounds. The two deaths after ovariotomy were not due to septicæmia, and are somewhat mysterious. One case was operated on at the patient's home in Bedford, Pa., and Dr. Goodell did not see her again. The cyst was par-ovarian, weighing forty-three pounds, was without an adhesion, and easily removed. The stitches in due time were removed, the bowels were opened, and everything did well for twelve days. Then obstinate vomiting set in, and the lady died on the seventeenth day. Six months previously she had had an analogous attack of obstinate vomiting, in which her life was despaired of. The fourth death took place from a supposed attack of malaria, to which the patient was liable. Both ovaries had been removed, the larger one weighing about thirty pounds. There were omental adhesions and very firm parietal ones, needing a number of ligatures. She recovered promptly from the operation, the wound united, the stitches were removed, and she was allowed to sit up out of bed. On the seventeenth day malarial fever, with bilious vomiting, set in, and she died rather suddenly on the twenty-first day, with symptoms of heart-clot.

Of the nine oöphorectomies, four were performed for ovaralgias, three for bleeding fibroids, one for epilepsy, and one for a menorrhagia, which had resisted every known therapeutic measure. In three cases of ovariotomy, all of them with papillary cysts, rupture had taken place a few hours before the operation; but although the peritoneum seemed thickened and injected, no bad result followed. He considered papillary cysts to be benign in the very great majority of cases, and that the danger from the escape of ovarian fluid into the abdominal cavity was very much overrated. He had not refused to operate in a single instance of ovarian tumor, no matter how low the patient

was or how firm were the adhesions. He had consequently had several exceedingly difficult operations. Out of his twenty-eight ovariotomies, there were twenty-one with adhesions. In four the adhesions were universal; in eight more they were intestinal; and in three they were uterine. This very large proportion of adhesions when compared with those of European operators, he could explain only on the theory that physicians in this country have not yet been educated up to the idea of an early operation, and to a recognition of the evils of tapping. In the successful operation of hysterectomy, a tumor weighing eight pounds was removed, together with a portion of the enlarged womb. As the uterine cavity was not invaded, the large pedicle was transfixed, tied, and dropped. The four exploratory incisions were made with the view of removing the ovaries, on account of the fibroid tumors of the womb. But in each the tumor was so fixed by adhesions that the ovaries could not be reached, and the patients had previously stipulated that in that case the uterine growth was not to be removed. All did well. So also did a case of pelvic abscess communicating with the bladder and rectum. It was opened per vaginam by means of the abdominal incision, by which its exact position and size were determined.

With regard to the technique of the operation for laparotomy, Dr. Goodell stated that he used the ordinary knot and the Staffordshire knot indifferently; that he now in the long incision cuts directly through the umbilicus, instead of going around it on the left side; that he includes the recti muscles and all the tissues in the abdominal sutures; and that while not a very firm believer in the spray part of antiseptic surgery, he had resorted to the atomizer in every case but one, and that one did as well without it as most do with it.

Dr. Montgomery thinks Dr. Goodell should be congratulated upon his success, which is remarkable for operations in unselected cases in the United States. He thinks the knowledge of the safety attending the application of Monsel's solution to oozing abdominal surfaces very gratifying. He would have used it recently but for the fear of bad after-effects. He must, however, again enter his plea for the second ovary. In young women small ovarian cysts are common; they are frequently found in post-mortem examinations when there had not been the slightest evidence during life of their presence; and evidently these small cysts do not necessarily develop into large ones. The two cases of secondary ovariotomy reported by Dr. Goodell are not sufficient to warrant the rule of removing the second ovary when it is but slightly diseased. As a counter-weight to Dr. Goodell's cases he would mention that in the instance of a young married woman from whom he removed an ovarian tumor, and in which he left the other ovary, which was slightly affected, pregnancy has since occurred, followed by the delivery of a living child.

Dr. Kelly remarked that Dr. Keith had had remarkably good results from the application to oozing surfaces of a solution of persubnitrate of iron. He has observed the gradual disuse of carbolic acid in washing waters in operations. Dr. Kelly prefers boiled or distilled water as used abroad, as he is sure that carbolic acid and other germicides are frequent causes of poisoning aud bad results after operation. He asked Dr. Goodell what were his rules respecting the use of the drainage-tube.

Dr. Baer had experimented with Monsel's solution. In one case in which he used it he attributed the fatal result to it. The coagulation by the iron is unsightly, and he should now consider it a last resort. He had had very good results from pressure by packing sponges against the bleeding points, combined with external pressure. He withdraws the sponges at the last moment before tightening sutures, and then bandages the abdomen tightly.

Dr. Goodell remarked that Dr. Montgomery was perfectly right in his defense of the second ovary, and he himself had performed double ovariotomy in only seventeen cases of the twenty-eight. He did not believe that every ovary studded with cysts would inevitably degenerate into an ovarian tumor. So in the case of slightly diseased ovaries in young married women he would be disposed either to let them alone or to remove the diseased portion only. But in women approaching the climacteric, or where other conditions would make it advisable, he would remove the second ovary as useless in itself, and as a possible source of future trouble. He has used the drainage-tube but three times during the past year; once in the unfinished case of oöphorectomy, again in the case of torn bladder, and in the case requiring over thirty ligatures and with universal adhesions. In general, he uses it when a free oozing of blood is to be expected, but he regards it as a source of trouble, and removes it as soon as possible.

W. H. H. Githens,
Secretary.

CHICAGO MEDICAL SOCIETY.

OFFICIAL REPORT.

Stated meeting, February 1, 1886. The President, C. T. Parkes, M. D., in the chair.

Dr. J. Suydam Knox read a paper entitled

Quinsy as a Rheumatism.

The author reported the treatment of fifty cases of the disease. In forty-five cases (95 per cent.) there was a positive rheumatic diathesis. Forty of these cases were cured in thirty-six to seventy-two hours, without suppuration. The treatment was salicylate of sodium, and hot alkaline gargles, or the repeated insufflation on the tonsils of bicarbonate of soda. Five cases, decidedly rheumatic, were not benefited by similar treatment. Five cases, not rheumatic, were not benefited, and at the end of forty-eight hours the ordinary treatment of quinsy was followed. Only one of these cases did not suppurate. The doctor concludes that a large majority of quinsies are rheumatic inflammations:

1. From the percentage observed.
2. From the success of anti-rheumatic treatment.
3. From the similarity between the symptoms of quinsy and rheumatism.

Dr. Knox said that wherever possible he used an insufflator and blew bicarbonate of soda directly on the tonsils, using as much as thirty grains, and allowing it to remain on the tonsils as long as possible, to be followed by a gargle of water as hot as could be borne, and to be continued until the throat was cleared, which would take from half an hour to two hours. He sometimes used carbolized lime-water, with morphia.

Dr. J. S. Knox said that he could not say as to every case, but that where suppuration takes place it is usually in the gland, an abscess is formed from glandular inflammation, and suppuration takes place through the gland.

Dr. A. B. Strong reported

A Case of Intubation of the Larynx for Acute Catarrhal Laryngitis, with Recovery.

He said the patient was a child, æt. 2½ years, delicate and small for her age. She had been sick thirty-six hours when it was decided that intubation was imperatively demanded, and it was done. Instant relief was obtained. The act of introducing a No. 3 tube had caused such an abundant ejection of the mucus, and the breathing was so easy, that the tube was withdrawn, and the child passed the night comfortably. However, at 4 p. m. of the succeeding day the tube was re-introduced with the same success, but about twelve hours after the child caught hold of the thread and withdrew the tube. The No. 2 tube was then placed in position and remained there sixty-eight hours, when recovery was complete. Dr. Strong said intubing the larynx has advantages over tracheotomy in being quickly performed, furnishing instant relief without cutting or bloodshed, being free from danger, and readily assented to by the parents. The care of the patient after operation is slight, as compared with tracheotomy, as the tube does not have to be interfered with, nor does it often clog up. The tubes as now made, those of Dr. O'Dwyer, are not easily coughed up. It is easier to introduce than remove the tube, owing to the fact that if the thread is left in the mouth it causes coughing and difficulty in swallowing. It was observed that during the thirteen hours the child wore the tube with the thread she had more difficulty in swallowing than subsequently when the thread was withdrawn, the thread being drawn across the epiglottis probably interferes with it closing the glottis during deglutition. Besides, the thread requires constant watching lest the child grasp it and withdraw the tube. Still, in case a mass of mucus should lodge against the lower end of the tube and stop respiration, the thread might be the means of saving the child's life by allowing the tube to be speedily withdrawn.

The President said it was a matter of surprise to him that so small an opening would allow the exit of secretions, as in the case just reported. It had been his experience that recovery always follows cases of catarrhal laryngitis. However, in these cases, he thought the introduction of the tube might be of great benefit in relieving difficult breathing or dyspnœa, and in allaying the fears of friends. He was aware that a very small opening gave air sufficient for inspiration for some hours. He once operated on a boy about five years old, in whom the trachea by improper manipulation was turned in some way, and the incision made in the side of the trachea. When the external tracheotomy tube was introduced into the wound, the child breathed quite well, the suffusion of the face passed away and the lips became red, but still the sound of the breathing was not satisfactory to the ear. He then tried to introduce the internal tube, and found the child had a return of all the symptoms of suffocation. On removing the external tube at the bottom of the wound the trachea was seen

unopened. The child recovered. The President said that while the tube was in this bad position he looked into it through the fenestra, and the bottom of the fenestra was an opening through which the smallest probe could be introduced into the trachea, which enabled the child to inspire air enough to relieve the urgent symptoms. He thought that in a case of true diphtheritic laryngitis an opening of the size of the tube under discussion could, in his opinion, not give exit to any such amount of secretion as is frequently seen during an operation. He did not think that intubation of the larynx would take the place of tracheotomy; it no doubt is of great benefit in those cases where the patient is likely to die unless some measure be quickly adopted which will give time enough to allow the operation of tracheotomy. In the case under discussion, the tube was worn sixty-eight hours continuously. He had not seen a case of tracheotomy where the closure of the fenestra gave evidence that the trouble with the larynx or glottis was overcome in less than six days. This was the shortest time in which he had been able to remove the tracheotomy tube.

Dr. F. E. Waxham said that from his experience with intubation of the larynx, he was thoroughly convinced of its utility, and its superiority over tracheotomy. He had eight recoveries out of his first seventeen cases, a result which he claimed could not be approached by tracheotomy, especially in Chicago. The ages of the patients varied from 11 months to 5 years; he considered these eight cases as being saved from certain death, as in only one case would tracheotomy have been permitted by the friends, and he had the corroborative evidence of other physicians as to the impending danger, and the urgent necessity of surgical interference. Since his last report he had had a number of cases, and had performed the operation four times during the last week, one patient being only 11 months old, suffering from both laryngeal and pharyngeal diphtheria; the urgent symptoms were at once relieved. In another case, aged 18 months, where death was impending, the tube was introduced without difficulty and the child relieved, and recovery would without doubt have been the result had not the child died of pneumonia on the second day. In another case, one of malignant diphtheria in a child of 2 years, the patient succumbed on the second day after the operation. In another case, he found the patient cold and livid, pulseless, and unconscious. After the tube was introduced, cold water was dashed on the child's face, and in about five minutes he looked around and asked for his father, took some milk, and passed into a quiet sleep. This child died from pneumonia three hours later. Dr. Waxham said that in the eight cases that recovered, in every instance false membrane was observed; when the tube was introduced, the membrane was ejected, either in large flakes or broken-down masses. He recommended that in treatment after intubation nothing at all irritating should be given, as when a child takes fluid of any kind a few drops will trickle into the trachea and cause violent coughing, and this irritation will often lead to pneumonia. In a child rugged and strong, bichromide of mercury may be given to hasten disintegration of false membrane. The most remarkable case coming under his observation was a child of 4 years upon the verge of suffocation, when, upon the tube being introduced, a considerable portion of false membrane was thrown out through the tube, and the violent symptoms subsided at once. The thread was removed, and the second day after the operation the child was playing about the room, and continued about the house during the four days that the tube was worn, and finally made an entire and perfect recovery. Dr. Waxham thought that in regard to the comparative value of tracheotomy and intubation very much might be said. The text-books give as the percentage of recoveries from tracheotomy about one in three, but these statistics are made up from the most favorable reports. If a physician has one recovery out of three or four cases he is justly proud of it, and reports the case; on the other hand, if there is one recovery out of fifteen or twenty cases no report is made. He had known one physician to have operated fifty times with but two recoveries. Dr. Waxham thought that the thread should always be removed, as it is a considerable cause of irritation, and that no difficulty need be experienced in removing the tube with extractors. He thought intubation had a grand future.

Dr. E. Fletcher Ingals did not take an enthusiastic view of intubation excepting for young children, when he thought it would be found more satisfactory than tracheotomy. In very young children tracheotomy does not result well, and he thought intubation would be unsatisfactory in older ones until we have larger tubes. He stated the accepted opinion of surgeons to be that a tube of less than one-fourth of an inch in diameter can not furnish sufficient air for a child to live on. Dr. Ingals thought that Dr.

Waxham had been remarkably successful with intubation, and had demonstrated its utility, for which he deserved credit. Dr. Ingals thought that intubation of the larynx is preferable to tracheotomy in children less than three and a half years of age; children much older than this cannot get a sufficient amount of air through the tube now in use. He said, also, that in performing one operation he had had trouble with the gag, which was not large enough for the child, a boy of five years, who lifted his teeth from the gag and closed them on the doctor's finger. He thought there was no need of the thread remaining, as there could be little difficulty in removing the tube. Dr. Ingals thought in cases where it is difficult to get the consent of friends, or where the conditions are such that tracheotomy cannot be performed right away, intubation would be of value; there are cases not membranous in which intubation may be of value. The statistics looked pretty bad for tracheotomy, but he had seen statistics of fifteen or sixteen cases where half of them were recoveries. His success had not been quite so good, but he attributed this mainly to the fact that he had operated on five children who were almost dead, or at least had stopped breathing before the operation began. He had the good fortune once to save a child who had not breathed for what seemed to him twenty minutes. One of the strong points in favor of intubation is that it may be done early, and it does no harm even if unnecessary.

Dr. H. T. Byford said there was another way of drawing the line which would more accurately describe the usefulness of the two operations. Intubation seemed to him the operation for private practice, and statistics so far are comparatively favorable to it as such. But the coöperation of the patient's friends, the preparation of the inspired air by passage through natural channels, the freedom of intubation from grave responsibility, its bloodlessness, the simplicity of treatment afterwards, as well as the greater rapidity with which the mucous membrane around the vocal chords will get well, are conditions which have less bearing in hospital practice, where we have trained nurses and all modern appliances, and there is more hope of success in tracheotomy. While he did not think this latter operation favorable for private practice, such advantages as having the tube under the eye, and within reach of the fingers, of an attendant, the ease of local medication, the possibility of removing shreds of membrane and plugs of mucus, and of inspecting the parts, by removing the tube, and the longer time the tube can be retained—these are things that do not pertain to intubation, and which, in hospital practice, must secure for it some consideration. He said that there was one clinical fact that had not been mentioned in this connection, yet which, more than all other things put together, accounts for the success of intubation and the failure of tracheotomy as life-saving measures: in the one the patient can cough, in the other he can not. After intubation the patient can normally close the glottis, compress the inclosed air in the lungs, and with sudden explosive force expel everything that is sufficiently loosened. This accounts for the fact that with such a small tube the patient experiences no difficulty. After tracheotomy the patient has no means of compressing the air and expelling it with sudden explosive force; he can simply inspire and expire forcibly, and after exhausting efforts get rid of a little of the mucus. This desperate condition of affairs has led some surgeons to employ the dangerous and barbarous custom of introducing feathers or other irritants into the tube to stimulate the mucous membrane, which excites the patient and scatters the mucus both upwards and downwards. When somebody invents an appliance which will enable the patient to really cough through the tube, then tracheotomy will be placed upon a rational basis, and will stand some chance of becoming a useful operation. The doctor thought tracheotomy had made a poor showing for its years of trial.

Dr. G. C. Paoli said that malignant diphtheria is a morbid poison, and that in epidemic cases there are very few recoveries. He stated that in such cases exudation takes place in the larynx or pharynx, and that an operation would only result in sending the patient more quickly to another world.

Dr. W. E. Quine said that he had operated twelve times for tracheotomy, and had not had one recovery in diphtheritic cases. He knew he was not alone in an experience of unvarying failure in cases of this kind; and he knew some surgeons now regard tracheatomy with very little enthusiasm. It seemed to Dr. Quine unfair to place intubation of the larynx in contrast with tracheotomy upon the basis of the assumption that tracheotomy is always a *dernier resort*, that it is done when the patient is absolutely moribund, and that intubation is done under the most favorable circumstances. This is not the fact. Dr. Quine said he was personally cognizant of two of Dr. Waxham's cases, in which the patients

were *in extremis*, and in which death would undoubtedly have occurred in two or three hours had not relief been afforded. Surgeons rarely had occasion to perform tracheotomy under more discouraging circumstances.

Dr. J. J. M. Angear said he wished to call attention to a physiological and anatomical fact that had not been alluded to, viz.; that the arytenoid cartilages are not mature, and that the chink of the glottis is held open by positive muscular action in small children, whereas in adults and older persons the arytenoid cartilages are mature and the chink is never closed. Dr. Angear said that a large number of children who suffocate will suffocate when there is no membrane present to cause suffocation, but simply some diseased condition that has interfered with the action of the delicate little muscles that draw back the arytenoid cartilages. When inflammatory action has interfered with these muscles drawing back the arytenoid cartilages, some mechanical interference like this tube will assist these muscles to keep the chink of the glottis open and let air in. He thought a large number of children who died of diphtheria did not choke to death, but died of poison in the system, and he did not think either the tube or tracheotomy, or any other process, could save them. If there was interference with the opening of the chink of the glottis he had no doubt the introduction of the tube would save the life of the child.

Dr. J. S. Knox said that the curse of tracheotomy are the subsequent thoracic complications, either heart clogs or congestion and inflammation of the lungs, producing fatal results, and the reason probably is that tracheotomy is the final resort in cases of laryngeal obstruction. He thought that if tracheotomy were performed as early as intubation, there would be fifty per cent. of recoveries. The great advantage of intubation is that it can be performed early, and the early operation of intubation would no doubt save many a life that tracheotomy would not save performed late. He thought that tracheotomy performed as early as intubation would show as good results.

The President said that he did not intend to say anything against the practice of intubation, but he did not believe that it would take the place of tracheotomy. Intubation has had but a very short trial, and it is not yet time to pronounce it better than tracheotomy. The early experience of the President in tracheotomy had been almost the same as that of Dr. Waxham in intubation. In the first fifteen cases operated on but half of them recovered, and his later experience was better than that reported by Dr. Waxham, as within the last month he had had three cases of tracheotomy, all recoveries, while Dr. Waxham reports four cases of intubation, all fatal. So far as his own personal experience went, he thought tracheotomy had the advantage. The President thought that if he should put a tube in a child's throat for the relief of laryngitis, and the child died without his having performed tracheotomy, he should consider himself very much to blame. He had no doubt that cases of extreme diphtheritic laryngitis got well after tracheotomy; he had seen diphtheria of the pharynx and of the larynx recover after tracheotomy. Although he did not feel enthusiastic about intubation, he thought it had a very good place, and in many cases might be very useful, but could never supply tracheotomy.

Dr. Waxham said he had never found the tube occluded when it was removed. In one case when he introduced the tube a portion of the membrane was crowded down ahead of it, obstructing it entirely, and the tube was ejected and was then completely filled with membrane; the child recovered subsequently. On removing the tube on the fourth or fifth day, he did not find it occluded.

Dr. A. B. Strong said, in conclusion, that he had had some experience with tracheotomy, having had twelve cases with but one recovery. He had no doubt that in cases of diphtheria the membrane could come up through the opening. The case read was reported as spasmodic croup, and was not supposed to be one of false membrane; but he believed the child would have died without interference, and that belief was shared by Dr. Danforth, the attending physician. Dr. Strong said that he would hardly feel safe in leaving the tube in the trachea of a child without the thread. He agreed with the president that large pieces of membrane could not readily pass through such a long tube. In the case reported the tube was entirely free from membrane or pus when taken out.

—Every ancient Egyptian considered it his duty to purify himself once a month by taking an emetic, then a purgative, afterwards a bath, as they very sensibly considered that most diseases arise from intemperance, and that bad diet and not God was responsible for their sickness.

EDITORIAL DEPARTMENT.

PERISCOPE.

Laparotomy in the Treatment of Penetrating Wounds and Visceral Injuries of the Abdomen.

Dr. Frederick S. Dennis thus concludes an article on this subject in the *Med. News*, March 6:

The conclusions at which I have arrived from a study of those cases which have occurred to me recently, together with many others during the past few years, and also from those cases reported by other surgeons, are these:

1. That penetrating stab wounds of the abdomen are less fatal than penetrating gunshot wounds, but that the former are fatal in too great numbers to content us with the older methods of treatment.

2. That if the stab wound has injured the intestine or any abdominal organ, laparotomy is indicated. That it may be indicated also in cases where the gut is not penetrated, but where the gut may become twisted as a result of the stab wound.

3. That in a penetrating stab wound regarding which doubt exists, the diagnosis should be made certain at once, in order to pursue a proper line of treatment. The indications for laparotomy should be extended also to injuries of any organs within the abdomen.

4. That laparotomy offers no great additional danger to the patient, if properly performed under the strictest antiseptic precautions.

5. That while the number of exploratory laparotomies in stab wounds of the abdomen afford insufficient data upon which to establish any fixed rule of practice, the same principle which is recognized in the performance of laparotomy for gunshot wounds of the abdomen is also applicable to penetrating stab wounds.

6. That the enlargement of the original wound for an examination of the peritoneal cavity will not enable the surgeon to exclude in all cases fecal extravasation, perforation, volvulus, or hemorrhage. These may all exist, and no evidences of their presence be manifest upon inspection through a small opening. My own experience accords with that of Prof. Weir, that enlarging the wound may or may not offer the essential knowledge.

7. The size, shape, character, and velocity of the bullet, the attitude of the patient, the kind of weapon used to produce a stab wound, seem to me to influence the question of laparotomy. Any and all of these injuries are likely to produce perforation; and if there is any value in abdominal section, it should be promptly performed, irrespective of the facts connected with the penetrating abdominal wound.

8. It is possible to have a fatal hemorrhage from the large venous trunks in the abdomen, and this hemorrhage not be discovered until the cavity is about to be closed, when an attempt is made to sponge out the bottom of the peritoneal cavity. This has occurred to me in two cases, in one of which I had closed seven openings, and in the other I had examined the viscera in the cavity. The hemorrhage was checked at the time of the opening, and was not apparent until the close of the operation.

9. That the sutures, if properly applied, will close the perforation in every case, no matter how lacerated these wounds are. The sutures will close the wound in case of resection of the gut, so that no leakage will occur if water is forced through the sutured intestine.

10. The success of laparotomy is to be attained where every arrangement is complete and perfect. Everything depends upon the preparation which is made for this operation, and the antiseptic conditions under which it is performed. The shock, the perforations, the resections of injured parts of the canal, and the after-treatment, are all important steps in this operation; but the one obstacle yet to be overcome in the management of these cases is the control of the hemorrhage from large venous trunks; and until this object is accomplished, the science of surgery in this operation cannot be said to have arrived at a state of perfection.

In the present unsettled state of opinion, it would seem best not to perform this operation in medico-legal cases without the full sanction and support of a consultation. The courts of law have recently agitated the question of the propriety and the justifiability of this measure in penetrating wounds, and the legal profession have already upon several occasions, to my personal knowledge, found refuge in this operation to defend a criminal on trial for murder.

When laparotomy is placed among the well-recognized operations in surgery, and

when all opposition to it has ceased, the credit of this great achievement will be due to the influence of the writings and teaching of the late Prof. Gross. As far back as 1843, he said in his monograph on the "Nature and Treatment of Wounds of the Intestines:"

"Here the most prompt and decisive measures must be resorted to, or the person will perish from peritoneal inflammation . . . It will not do for the surgeon to fold his arms and look upon the scene as an idle and uninterested spectator. Far otherwise. He has a duty to perform, and that duty consists in dilating the external wound if it be not already sufficiently large, in hooking up the injured bowel, and in closing the solution with the requisite number of stitches, at the same time that the effused matter is carefully removed with tepid water and a soft sponge."

The remarks of the late Dr. J. Marion Sims gave new impulse to these views enunciated by Dr. Gross nearly half a century ago, and these theoretical opinions were again supplemented by the distinguished work of Dr. Parkes, of Chicago, who made a practical application of the theory in his researches and experiments upon lower animals. It remained for Dr. Bull to make the practical application of this knowledge available to higher uses, and thus step by step, through nearly half a century, we have arrived at the accomplishment of our object. It is a source of national pride, that laparotomy in penetrating wounds and visceral injuries of the abdomen was conceived, developed, and perfected in America.

A Case of Reflex Vaso-Motor Neurosis Dependent on Ovarian Displacement.

Dr. H. J. Boldt thus writes in the *Amer. Jour. Obstet.* for February:

F. L., æt. 16 years, began to menstruate at 13. At the time of her first menstrual period she noticed a purple discoloration of the entire right upper extremity, interwoven with white spots; at the same time a swelling manifested itself on the lower part of the right leg and foot, the latter, however, without change in color.

The entire upper extremity always felt cold during menstruation. These changes began one day prior to menstruation, and would reach their height on the fifth day, gradually disappearing in from two and a half to three weeks, to begin again at the next epoch.

One year ago the condition below described took place for the first time. One day prior to the beginning of menstruation, the right upper extremity began to swell and became discolored, of a purplish-blue color, interwoven with white spots, the swelling reaching its maximum on the fourth day, six weeks elapsing before its entire disappearance. The arm felt cold, and numbness and formication was complained of throughout the entire extremity; at the elbows the formication and "tingling" were felt quite severely. In the shoulder a tearing pain was felt, lasting about half an hour, and recurring twice daily. The entire right lower extremity had a very tired feeling one day previous to and during menstruation, which occurs at regular intervals of four weeks, lasting usually three days. Patient came to my clinic on account of an excruciating pain in the right inguinal region, from which she has suffered since the time of her first menstrual flow. The pain begins one and a half to two days prior to menstruation, and continues during the same. For the past year, however, the pain has been increasing in severity. Incidentally my attention was called to the swollen and discolored right hand, when the above history was obtained, and I had the opportunity to show the interesting case to several of my colleagues.

Status præsens.—The swelling is of stony hardness, not tender at any point, pitting but slightly, of deep purple color, intermixed with pearly white patches about the size of a lentil.

	Measurements. Right.	Left.
Wrist	6¼ inches,	5½ inches.
Middle of forearm	10½ "	7¾ "
Elbow	10 "	8½ "
Middle of arm (upper)	11¼ "	9 "
Near shoulder joint	12½ "	10¼ "

The superficial veins and capillaries of the entire right upper extremity, and the superficial veins of the anterior upper surface of the thorax, are intensely engorged, the posterior ulnar veins feeling like a hard cord.

Vaginal examination shows the uterus anteverted, freely movable, not painful.

The right ovary is prolapsed in the cul-de-sac of Douglas, and its corresponding tube is readily traced; the ovary is enlarged to about twice its normal size, very painful to touch; moderate pressure on it produces nausea, with desire to vomit. The present is the third attack (of swelling) within one year.

The result obtained from the treatment employed goes toward proving that the condition described is a reflex vaso-motor neurosis, dependent on ovarian lesion or displacement.

The patient, as noted above, had three attacks of swelling within one year, and al-

ways, from the time of her first menstruation, severe pains in the right inguinal region, with slight pain in the lumbar region, also always the very marked discoloration of the upper extremity, with swelling of the lower part of the corresponding leg and foot.

For three weeks she received regular treatment, consisting of galvanism as strong as could be borne without causing severe pain, and applications of iodine and glycerin tampons to the affected ovary. At her last menstrual period she had no pain whatever, for the first time since this physiological process began; the swelling (which had not fully subsided since her last menstrual flow) did not increase, neither did the discoloration become as marked as previously, and the swelling of the lower extremity remained absent.

Quinine Idiosyncrasy.

Before the New York Clinical Society, Dr. W. H. Katzenbach related the case of a nursemaid for whom he had prescribed quinine in the form of two-grain pills early in the day, who went to his office at 5:45 p. m. highly excited and in great distress. Her face was flushed, and her hands and arms were red. She complained of giddiness, mental confusion, and an inabillty to remain still. She had taken one pill at five o'clock, and in thirty minutes experienced—in her own words—"burning pain in the stomach and prickly heat all over." Her mouth and the parts behind the ears were very sore. There was great pain in the top of the head, and in the lower part of the body and the thighs. The breasts were swollen and painful. Her pulse were rapid and not strong. No examination was made. She was advised to go home and to bed at once. Sodium salicylate and sodium bromide were ordered in doses of five grains each, to be taken every hour, and the patient was requested to send word in the evening if she was not relieved. The speaker did not see her until the next day. She further said in her description that, on her way from his office to her home, she could scarcely walk straight, and feared she might be seen by a policeman and arrested for intoxication. She took one dose of the salicylate and bromide, but shortly vomited it. The burning pain left the stomach. The tongue and throat felt swollen, the pain increased in the head, and she had "a feeling of being smothered." At 7 p. m. she fell on the floor unconscious. When consciousness was regained she took another dose of the salicylate and bromide. Her legs were painful and heavy, refusing to support her. A cold perspiration came on, which continued some time, during which her bowels were moved. A third dose was afterward taken. At 10 p. m. the pains had left her head and extremities, but fullness of the head remained. She slept, off and on, from this time till morning, and awoke feeling well. Her urine was retained from the time of taking the quinine until the next morning.

"These symptoms," said Dr. Katzenbach, "were undoubtedly caused by the quinine. She had a similar experience in England a few years ago from a dose of five grains. She was reluctant to take what I had ordered, and did so after considerable persuasion by a friend."

Dr. Griswold has seen cases of eruption following the administration of quinine. He did not believe the amount of the drug taken was of any importance, small amounts, in his experience, producing the same effects in cases of quinine idiosyncrasy.

Dr. L. E. Holt had had a case in which, after cinchonidine had been taken, an eruption appeared very similar to that produced by belladonna.

Dr. T. H. Burchard believed that all skin lesions were apt to be aggravated by quinine. He had had a patient, the subject of chronic eczema, for whom, on account of some malarial manifestations, he had ordered twenty grains of quinine a day. In forty-eight hours the patient had an acute exacerbation, and was laid up with an attack of acute general eczema. Six months later the same result followed the use of Warburg's tincture. In a second case, that of a young lady who suffered from chronic erythema nodosum, an exacerbation with gastric disturbance followed the use of butter, and a single large dose of quinine induced an acute attack of the ulcerative form.

Antipyrin and Calomel Compared in Pneumonia.

The *St. Petersburg Weekly Clinical Gazette* publishes some observations which have been made by Dr. Posadski, under the direction of Prof. S. P. Botkin, on the comparative results of the antipyrin and calomel treatments in croupous pneumonia. He thus treated a group of twenty-five cases with antipyrin alone, giving from half a gramme to two grammes (seven and a half to thirty grains) for a dose, and one to eight grammes (fifteen grains to two drachms) per diem. A second group of twenty-three cases, as similar as possible to those of the first group, was treated with calomel in doses of one-eighth

of a grain four times a day. The average age of the patients in the first group was twenty-seven years and a half, and that of those in the second twenty-five years and a half. Those treated with antipyrin retained their full consciousness, but in the course of two or three days failed greatly in strength, the heart's action becoming exceedingly weak. They suffered from cough, and with difficulty expectorated a small quantity of slightly-tinged sputum. After the first few doses there was a fall in the temperature, but not of a permanent character; sometimes, indeed, there was no fall at all, and when there was, notwithstanding the continuance of the drug, a rise followed. The crisis took place with a fall of temperature on the average on the seventh day of the disease, the mean number of days of fever being 8.1, but the local physical signs lasted 13.5 days. Complications occurred in nearly all the cases, sometimes being of a serious nature, collapse even being noted. In the urine there was nearly always albumen in considerable quantity, also antipyrin. The fall in weight averaged 20.34 zolotniks (about twenty-seven ounces), which was less than the mean fall of the patients treated with calomel, but the latter recovered their weight more rapidly during convalescence. When the doses of antipyrin were frequent, vomiting was often induced, and in two cases an antipyrin rash made its appearance. Those treated with calomel frequently presented a typhoid condition, and in some cases there was delirium. They were not much distressed by cough, the sputum was expectorated easily and in considerable quantity, and they did not suffer from sweats. The temperature rose high. The mean duration of the fever before the critical fall was 7.1 days, which was generally accompanied by drenching perspiration. The local physical signs lasted on the average nine days (against 13.5 in the other group). There was rarely albumen in the urine, and when it existed there were only traces. Complications were infrequent. The general conclusion arrived at was that antipyrin, in spite of its power of reducing fever, has no beneficial effect on the course or result of the disease.

Lead-Poisoning by Household Utensils.

The German Parliament has now under consideration a bill which is intended to regulate the employment of lead in the manufacture of cooking and other domestic utensils, and so to diminish the risk of poisoning by that metal. The provisions of this measure certainly do not err on the side of leniency. They forbid the use of vessels containing more than ten per cent. of lead in their composition for the above purposes. No alloy with over one per cent. may be used in coating iron articles used in cookery. Solder may consist of lead to one-tenth of its amount, but no more. Enamels into which lead enters are treated with equal stringency. The effect of this bill, if it be passed, will be to obliterate the legal existence of pewter and of soft solder as at present made, since these alloys contain from one-half to one-fourth of their weight of lead. One fact which it brings into prominence is that lead-poisoning in Germany appears to arise from other causes besides those to which it is commonly attributed in this country. Cases of this kind among ourselves are usually found in the persons of those who are actually engaged in handling lead or its compounds in their daily occupation. Plumbers, painters, glass-blowers, glaziers, potters, and enamel-card makers furnish the majority of those who suffer from plumbism. When this disorder appears in the household, new paint in the walls or the lead work of the water service affords a clue to its detection. It is comparatively rare to find in these days that pewter pots or cooking utensils are at fault. This may be because glass is used on the whole far more frequently than pewter in the liquor trade; while in the kitchen those vessels, the contents of which are most likely to become contaminated with lead in the solder—such, for example, as preserving pans—are usually made of brass or copper (which is kept well burnished), and present a relatively trifling soldered surface, or are lined with porcelain. The water used in cooking also acts as a protective, since the lime-salts contained in it tend to prevent the solution of lead. The proposed German legislation on this subject is very perfect in theory so far as it goes. Possibly it may be called for by the teaching of experience. In this country it would probably be found to be needlessly severe, and would not cover the chief causes of the evil which it is intended to meet. We do not see how it can do this even in Germany, unless measures of equal rigor be adopted to control the use of lead in manufactures and in its other domestic applications. The introduction of these further restrictions might fitly exercise the judgment of our own as well as foreign legislators.

—Dr. Don Salustiano Fernandez de la Vega, Professor of Anatomy, has been appointed Dean of the Medical Faculty of the University of Zaragoza.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

ATTEMPT AT BACTERIO-THERAPEUTICS.

It has of late often been said that the discovery of pathogenic bacteria, even admitting the theory to be true, would probably lead to no important therapeutical results, for drugs, which really possess bacillicide properties, have to be administered either in doses so large as to threaten life, or locally directly to the diseased spot, which is but seldom possible without endangering the very existence of the individual.

But recently a new method has been discovered, which promises to give us better results. An Italian professor, Dr. Arn. Cantani, of Naples, who has acquired during the last few years a well-merited reputation for his original researches, the care with which he executed them, and the reliability of the results he obtained, as appears from a preliminary communication of his to the *Centrlbl. f. d. Med. Wissensch.* (29, 1885), has investigated the therapeutical value of the new theory, and taken a step in a direction differing greatly from that of all his predecessors in the same field.

It had long been looked upon as a well-established and indisputable fact that some species of bacteria have a destructive influence upon the culture of others, especially pathogenic microbes, provided they are brought in contact with them in a certain manner, and at the right time of maturity. This fact caused C. to conceive the idea to try in an experimental way its application to the therapeutics of some infectious diseases. He first endeavored to combat Koch's tubercle-bacillus with the exceedingly common bacterium termo, after he had convinced himself of the perfect innocuousness of the bacterium termo by various injections and inhalations practiced on animals. A woman, aet. 42, had in the left apex a large cavern. The patient was very weak and greatly emaciated, suffered from a febrile temperature every night, and expectorated large quantities of a purulent sputum containing elastic fibres and numerous tubercle-bacilli. A pure culture was made of bacterium termo and largely diluted with beef tea, a constituent portion of which was nutritious gelatine. This diluted pure-culture the patient was made to inhale by aid of an atomizer provided with two rubber balls, so as to insure uninterrupted atomization. The quantity of the expectorated purulent masses rapidly diminished, and finally the latter ceased completely; at the same time the tubercle-bacilli, which were formerly contained in the sputa in such great numbers, became less and less, and had totally disap-

peared by the end of the first month, while bacterium termo increased in number in the same ratio as the tubercle-bacillus diminished. The temperature also declined, and ultimately never reached higher at night than half a degree above normal; the patient increased during this period twenty-two pounds in weight, and her general health, as well as her physical strength, had greatly improved.

Certainly it is still too early to draw definite conclusions from this single case, and Dr. Cantani published this preliminary report only to draw the attention of other observers to this new field. If we take into consideration that the septic bacteria, for instance, whenever they penetrate into the tissues inhabited by any other species of pathogenic micro-organisms, soon multiply to such a high degree as to cause a destruction and total disappearance of the other bacteria, the method of C. appears plausible enough, and ought to receive a more extensive trial. At the time of Koch's discovery of the comma-bacillus of cholera, some of his opponents, though also experts, published the fact that they had not succeeded in finding a single comma-bacillus, notwithstanding their careful investigations of the fluid contents of the bowels of patients who had died of cholera. Koch explained the apparent paradox as follows: As long as the intestinal mucous membrane is only inflamed, innumerable comma-bacilli in their pure culture are invariably present in cases of Asiatic cholera, but later necrosis of the tissue sets in, induced by septic bacteria, that immigrated and found a suitable soil for their development. From the moment of their appearance, generally the fifth or sixth day of the malady, the comma-bacilli diminished in number in the same ratio as the septic bacteria increased, until by the ninth, tenth, or eleventh day in fatal cases, when the septic process had led to a complete destruction of the tissues, not a single comma-bacillus remained, while the bowels were crowded with septic bacteria. This explained the absence of the comma-bacillus in other cases of cholera, and also showed why such patients, after the specific cholera symptoms had ceased, presented the picture of individuals suffering from a low typhoid condition.

The most important result of Cantani's researches is the fact that so innocuous a microbe as the bacterium termo has the same fatal effect on tubercle-baciili as the septic bacterium has been proven to possess on the comma-bacillus. The discovery would be of immense value, and be paramount to a cure of tuberculosis; it is too good almost to believe it, but Cantani's reports thus far were so truthful that we recommend at least a further trial.

NEW METHOD OF DISINFECTION.

Prof. A. Dobroslawin, in Petersburg, has invented a stove peculiarly constructed, where by adding common salt to water (which evaporates only at 108° C.) he obtains a higher temperature, and thus by employing the heat, rooms and materials of all kinds may be disinfected.

In 100 parts water

41.2 parts common salt gave the boiling point at 108.4° C.
61.5 parts nitrate of ammonia gave the boiling point at 121° C.
205 parts carbonate of potash gave the boiling point at 135° C.
325 parts chlorcalcium gave the boiling point at 175.5° C.
88.9 parts colorcalcium gave the boiling point at 114.2° C.

With a solution of common salt the boiling point is reached in from two to three hours.

The following results were obtained:

	I.	II.	III.	IV.	V.
			Hours.		
The thermometer showed after	3½	2½	3½	2	4
If kept free in the disinfection			Degrees.		
space	106	105	105	107	106
20 times surrounded by a bandage	101	—	—	104.2	—
Between two pillows	101	—	90	100.2	—
In a carpet	—	103.5	—	—	102
In a bag full of wash	104	—	90	—	—
In a bag full of clothing	—	105	—	—	—
Wrapped in cloth pantaloons	—	—	100.5	100.5	—

To test the effect on micro-organisms, silk threads saturated with spores of bacillus subtilis were killed within three hours. In Experiment III, the door of the disinfection-space had been left open by accident. The stove costs about $120, and is made of metal in St. Petersburg, Russia.

ADONIDINE.

We have been asked by a correspondent in reference to the dose and uses of this drug. In reply, we would say that there appears nothing in the literature on the dosage of adonidine up to recently, although its physiological effect had been closely studied for some time. Upon inquiry of Professor Bartholow, he kindly referred me to an article by Dr. Armand Durand on the clinical use of adonidine, which appeared in the *Bulletin General de Therapeutique* of January 30, 1885.

From the article of Dr. Durand it would appear that the average dose of adonidine is 2 centigrammes ($\frac{1}{10}$ grain) in 24 hours, administered in pill form. This dose was in some of the cases he quotes increased to 4 centigrammes ($\frac{2}{3}$ grain) in 24 hours. And in the case of a fourteen-year-old child 20 centigrammes were administered in 24 hours

by a mistake, with the effect of producing a very acrid taste, vomiting, diarrhœa, and protracted nausea.

The dose of the leaves of adonis vernalis, as given by Bubnow, in infusion, was 4 to 8 grammes in 180 grammes of water in six hours.

We will be able to furnish further information on the subject of adonidine in a short time.

THE INTERNATIONAL CONGRESS.

Once more we are compelled to take the *Medical Record* to task for the inaccuracy of its statements. In its issue of March 6, we read:

"The prevailing feeling here regarding the Congress now is one of profound apathy and indifference. The news from abroad is equally discouraging. Almost the only smiling face is published at Chicago weekly. We hope for better news after the St. Louis meeting."

If the editor of the *Record* was a thick-headed Gothamite, we might believe that this wilful attempt, weak though it is, to injure the Congress, was the result of stupidity; but as we believe him to be a progressive American, we can only characterize it as a lame effort to say something in the direction which his journal has pursued. Now for the truth: there is a certain amount of "profound apathy and indifference" among those few who *would* but *could not rule*, while among the very great mass of the profession there is a lively interest in the coming Congress, and a determination to make it a success. The committee is at work, and all preliminary preparations are being satisfactorily made.

NATIONAL SANITARY CONVENTION.

We would call the attention of our readers in an especial manner to the announcement from the State Board of Health of a sanitary convention to be held in this city in May next. One of the most pregnant evidences of the march of civilization is the interest that is being taken of late years in preventive medicine. The researches of scientists by which the intimate cause of disease has been in many cases fathomed, has not been as yet productive of much result from a therapeutic standpoint; but they have furnished to the sanitarian the most powerful weapons with which to prevent the inroads of disease.

This convention, we understand, is but the beginning of a crusade on the part of the State Board of Health, having for its purpose the fostering of this awakening interest in sanitation among the people, and we sincerely trust that our readers will use their great influence to make the convention a pronounced success.

We would ask our exchanges to kindly copy this circular, and editorially help the convention.

Notes and Comments.

Genital Irritation as a Cause of Reflex Nervous Phenomena.

We have taken occasion to call attention to this condition in several previous issues, but more especially in reference to children. We are pleased to note that so high an authority as Dr. Lewis A. Sayre, of New York, calls attention to its occurrence in the adult in the *Virginia Medical Monthly*. We reproduce his own words:

"Mr. M——, aged twenty-five years, an unusually well-developed, muscular man, but exceedingly nervous, came to me suffering from an injury to the spine from the plunging of his horse while horseback riding, producing almost complete paralysis of the lower extremities, being unable to stand or walk without assistance, and suffering intense pain in the lumbar region. He was at once leeched, and this treatment was followed the next day by dry cups along the seat of the injury, and he was retained in the horizontal posture for some weeks. During this enforced quietude, my attention was directed to his extreme nervousness, which amounted almost to hysteria; and on examining his penis, I found this organ in a state of erection; the prepuce was firmly constricted around the glans, and it was with great difficulty it could be pushed behind the corona. The frænum was so very short as to draw the urethral orifice backwards and open. The least touch upon the meatus produced a peculiar nervous spasm of the entire body. The prepuce being drawn behind the glans, a thin white line was to be observed girdling the entire penis, and he complained of this causing him great pain. He then informed me that he suffered from constant erections of the penis, frequently lasting from twelve to eighteen hours. In many instances while in the society of ladies he would be compelled to leave the room, and frequently while horseback riding he would have to get off his horse and abandon this exercise, as the penis would become so irritable and

erect that semen would pass involuntarily from him.

I divided this girdling band upon the dorsum of the penis, and then divided also the frænum, tearing the latter down to the extent of nearly an inch, thus allowing the glans to assume its natural appearance, and removing all constriction.

Since the operation his nervous system has undergone a complete and entire change, and he will now leave on an extended European trip.

In the *Peoria Med. Mo.* for August, Dr. Frank L. Hinsdale reports a case of convulsions in a boy aged five, caused by phimosis. An operation effected a cure.

Epidemic of Cerebro-spinal Fever.

During February and March this year, an epidemic of cerebro-spinal fever existed in Oppan (Pfalz). A report of it by Dr. Demuth has now appeared in the *Vereinsbl. d. Pfalz, Aerzt.*, 6, 1885.

Dr. D. attended 16 cases; 9 of them were fatal. Prodromes were almost always absent, and the disease began abruptly with a violent chill, vomiting, and headache; at the same time stupor developed, often at once followed by coma; rigidity of the neck recently appeared within a few hours after the chill, and hyperæsthesia in a high degree was noticeable even during stupór. Jactitation was frequent, and unilateral convulsions generally occurred before death. Usually by the third day vomiting ceased; the stupor alternated with movements during which the sensorium was clear; temperature and pulse diminished, but the latter was at times irregular. Herpes labialis occasionally appeared, and the stiffness of the neck augmented rather than diminished. Convalescence began at some time between the ninth and twenty-first day.

Three main types were noticed: 1. Very acute, violent cases, at once fatal; 2. Grave cases with violent beginning and an acute course, which, however, continued longer, ending in death or convalescence; 3. Milder cases, same beginning, but after the third day rapid amelioration of all phenomena, depression specially noticeable, and without other accident recovery soon set in.

Here, as in other places, the disease was at its height during the first four months of the year. D. believes the disease to be due to infectious material, and to be propagated by drinking-water; schools he considers the main centres of infection. Children and young adults were mainly the victims. Rheumatism and pneumonia were specially frequent at the time. In only one case was herpes labialis absent the third day. D. does not mention ecchymoses, and his treatment contains nothing new. He mainly relied on mercury, and did not at all use opium.

Laryngeal Spasm Caused by Cocaine Spray.

That we cannot use this drug without a certain amount of caution, the following case which Dr. F. De Haviland Hall reports in the *Lancet*, November 21, gives evidence. To use his own words:

"P. R., a lady of the age of fifty-six, came under my care in July, suffering from asthma. On examination, I found both nostrils filled with mucous polypi. She had frequently been operated on, the last time six years ago. In six sittings I completely cleaned the nostrils by means of the electric cautery; the patient, who had much experience of other forms of treatment, expressed her opinion most decidedly in favor of the plan adopted. Cocaine in a 20 per cent. solution, applied with the brush, greatly facilitated the operation by abolishing the sensibility of the mucous membrane, and by the power it has of causing contraction of the erectile tissue of the nose, thus enabling the operator to get a good view of the posterior part of the nasal cavities. As the patient found the heat of London very trying, it was agreed that she should go home and return for the completion of the treatment in October. Accordingly, she presented herself on October 5th. Since the patient's last visit I had bought the cocaine spray apparatus introduced by Dr. Miller, of Windsor, and, as I had used it frequently before, I began to spray the interior of the patient's nose with 10 per cent. solution. The nostrils, being no longer blocked, allowed the spray to pass into the throat. In the course of a few minutes the patient complained of a feeling of cramp in the throat. She soon became very excited, stood up, and gasped for breath; her countenance assumed an ashy hue, the hands were cold, and the pulse very frequent and feeble. Inspiration was attended with a roaring sound. Speech was not affected. There was deficient entry of air over the chest, but no abnormal sounds were audible. The symptoms clearly pointed to spasm of the abductors of the vocal cords, a condition resembling laryngismus stridulus. The distress was so great that I did not venture to suggest a laryngoscopic examination. With difficulty I persuaded the patient to

recline on a sofa, and I administered chloroform, which relieved the spasm, but she was not sufficiently recovered to leave my house until after the lapse of four hours from the commencement of the attack. Next day she was in her usual health. A few days later I completed the treatment by destroying with the galvano-cautery the mucous membrane from which the polypi sprang, taking care, however, to apply the cocaine with the brush, and not to allow any to enter the throat. The patient is distinctly neurotic, and had suffered from similar though slighter attacks on two previous occasions.

"That this is quite an unusual accident in the employment of cocaine is shown by the fact that, though I have frequently applied a 20 per cent. solution directly to the larynx, the only complaint I have had has been on account of the bitter taste of the drug."

Treatment of Tænia.

Dr. Berenger Frank, who, as director of the French navy, had an enormous material at his disposal, publishes in the *Bull. Général de Therap.*, Oct. 30, 1885, the results of different remedies for the removal of tapeworm. Of 1842 cases, 425 were treated with success, 1417 without any, i. e., the tapeworm always returned. The following remedies proved useless: Calomel, ocean salt, garlic, eucalyptus, extract of kousso. Very little effect had ether, turpentine, felix mas; more had kousso, and the best results were obtained with pelletierin; of 317 cases treated with it, 198 permanently recovered. The method employed was as follows:

The day before the administration of the drug the patient takes no other nourishment but milk; the day of treatment he stays in bed and receives at 6 a. m. an infusion of senna (160–240 grains to 5 oz. water). At 7 a. m. the first dose of tannate of pelletierin (6½ grains) is taken in syrup, and half an hour later he receives the second dose, always remaining in bed to prevent vomiting. At 8 a. m. a dose of castor oil is administered, which, if action does not soon set in, is followed by a senna-clysma. The tapeworm is collected as usually.

We do not wonder at the comparatively small result of Dr. F.'s treatment for tapeworm. In an experience of twenty-two years, during which we had occasion over a hundred times to treat such cases, we have never known an instance when the ethereal extract of felix mas had not established a cure, from 2½ to 3 drachms being the dose of this remedy, which we consider far more reliable than any other. The evening before the patient eats something salty for supper, at 9 p. m. he takes half of the remedy, at 9:30 the other half, and the next morning at 5:30 a. m. a dose of castor oil. An hour or two later the tænia appears. The best manner to prescribe the remedy is as follows:

℞. Extr. felic. maris æth. ʒiss–ʒiij.
Emuls. amygd. dulc.
Syr. simplicis, āā. q. s. ad. fl ʒiv–S.

Treatment of Bronchitis.

We cull the following formulæ from a paper by Dr. J. Milner Fothergill in the *Med. Record*, August 29, 1885:

In the stage of *excessive secretion* he recommends—

℞. Amm. carb., gr. iv.
Tinct. nuc. vom., ♏ x.
Inf. cinchonæ, ℥j.
4tâ vel 6tâ horâ.

If the case is not very severe we may use—

℞. Liq. atropiæ, ♏ j.
Liq. am. anisat., ♏ xv.
Aq., ℥j.
M. 6tâ vel 4tâ horâ.

If the case be mild, then—

℞. Ac. hydrobrom., ʒss.
Sp. myristicæ, ♏ ij.
Syr. scillæ, ʒss.
Sp. chloroform, ♏ xv.
Aq., ℥j.
M. Three or four times daily.

In *chronic bronchitis* we may give—

℞. Strychniæ, gr. $\frac{1}{24}$.
Pulv. ipecacuan., gr. $\frac{2}{3}$.
Pulv. digitalis, gr. $\frac{1}{3}$.
Pil. galban. co., gr. ij.
Bis aut ter in die.

If the bowels are not regular, a small quantity of podophyllin or croton oil may be added.

To secure rest at night we may use—

℞. Bromidi ammonii, ℈j.
Tinct. camphoræ, ℥j. M.

Or,

℞. Morphiæ mur., gr. ¼.
Benzoic acid, gr. j.
Pil. scillæ co., gr. ij. M.

A Case of Dissecting Aneurism of the Thoracic and Abdominal Aorta.

In the January number of *The American Journal of the Medical Sciences*, Dr. James E. Graham, of Toronto, describes a case of dissecting aneurism of the aorta which presents many points of very great interest. The patient lived after the first formation of the aneurism, a period of more than thirty

years. The strain was taken off by an opening low down between the artery and the aneurism, which rendered it possible for the blood to flow readily back into its old channel. The aneurism extended throughout the whole length of the abdominal and thoracic aorta, and more than half the circumference of the vessel. The closing of openings in the inner coat, at the exit of arteries from the aorta, and the corrugated appearance of the inner surface of the aneurism, are also points worthy of notice in this remarkable case, which is an excellent example of the restorative power of nature, and demonstrates the possibility of the enjoyment of years of fairly good health in one suffering from an extensive dissecting aneurism.

The Treatment of Cholera Infantum.

Dr. J. H. Carster gives us the following formulæ in the *Archives of Pedriatics:*

For the vomiting:

℞.	Tinct. iodi.,	gtt. x.
	Aquæ,	℥ij.

M. Teaspoonful every half hour.

In some cases he uses a powder composed of

℞.	Subnitrate of bismuth,	1 drachm.
	Dover's powder,	3 grs.

To be divided into twelve powders, one every two hours.

This often does in mild cases. Sometimes, however, if there seems to be a malarial complication he gives quinine, for instance something like this:

℞.	Sulphate of quinine,	10 grs.
	Tincture of opium.	20 drops.
	Syrup Yerba Santa,	2 ounces.

M. S.—Teaspoonful every two hours.

In so-called chronic cases—that is, after the vomiting has ceased, but diarrhœa continues ten or twelve times a day, he generally depends on a mixture like this:

℞.	Tincture ofopium,	½ drachm.
	Chloroform,	20 drops.
	Whisky,	1½ drachm.
	Cinnamon water	6 drachms.
	Simple syrup,	1 ounce.

Teaspoonful every two hours.

When the diarrhœa checks, he only gives it every four or six hours. Also, during this stage, when the disease has subsided, he gives:

℞.	Nitro-muriatic acid,	15 drops.
	Pepsin,	1 drachm.
	Water,	2 ounces.

Teaspoonful every three hours.

This seems to aid digestion. In some cases the discharge seems to be checked up too quick with any of these remedies, and we get symptoms of congestion of the brain, so-called false hydrocephalus, and the child is very liable to go into convulsions. In such cases, he always gives bromide of potassium, and some cathartic. Start up the bowels again and relieve the cerebral congestion. He generally gives about one-twentieth of a grain of podophyllin. In all cases of cholera infantum, it is especially necessary to carefully watch the effects of opium, when we use it. He believes in being very cautious in prescribing opium.

If, however, the disease progresses to the stage of collapse, active stimulants will be necessary. In such cases, he thinks belladonna is especially useful, combined with other stimulants as follows:

℞.	Fluid ext. of belladonna,	1 drop.
	Compound spts. of ether,	½ drachm.
	Water and simp. syr., each,	1 ounce.

Teaspoonful every two hours.

Besides that, give whisky or other stimulants, apply hot bottles to the feet and body. The hypodermic injection of ether and whisky is also sometimes of benefit, and when there is very high temperature, the use of ice to the head will be useful.

Treatment of Intestinal Obstruction by the Force-Pump.

Dr. H. Illoway, of Cincinnati, in a paper in the January number of *The American Journal of the Medical Sciences,* advocates the employment of enemata administered with sufficient penetrating power to pass beyond the ileo-cæcal valve and into the small intestines, and to produce peristaltic action. He advocates the use of the force-pump, and claims first, that enemata thus administered are superior to every other method of treatment in the rapidity with which they either relieve the symptoms or clearly indicate the necessity of surgical interference; second, that they are entirely free from all danger, and in no way prejudice the case should a surgical operation become necessary.

Remedy for Corns.

Dr. J. Sutcliffe Hill tells the *New England Medical Monthly* that some time ago he was fortunate to find a prescription that has proven, in his hands, of much value in removing corns. It is:

℞.	Ext. cannibus indicus,	grs. xv.
	Salicylic acid,	grs. xxx.
	Collodion,	℥j.

Sig.—Apply with brush.

Correspondence.

Paris Letter.

M. JULES GUERIN—M. DECHAMBRE—SENATOR ON TYPHOID FEVER—GERMAIN SÉE'S CLINICAL MEDICINE—ASTHMA—PYRIDINE — HYPNONE — URETHAN — COCAINE IN GASTRALGIA—TREATMENT OF EMPYEMA —RETAINED MENSES AT A VERY EARLY AGE.

In my last letter I spoke of M. Jules Guerin and his determined opposition to Pasteur's theories of inoculation for rabies. Since then he has passed away at the ripe age of 85, having passed somewhat more than fifty years as a prominent medical writer and observer in Parisian medical circles. He bought and became editor of the *Gazette Medicale de Paris* in 1830, and has since made it one of the most popular medical journals of Paris. He was very decided and even obstinate in his opinions, and made himself particularly remarkable in late years for his determined opposition to the germ theory and all the discoveries of Pasteur.

Another very able medical publicist, M. Dechambre, the editor of the *Gazette Hebdomadaire*, and of the new *Dictionnaire des Sciences Medicales*, also died rather suddenly from cerebral apoplexy. He was a very elegant writer of French, and has written a large number of articles in his journal and in the *Dictionnaire*. He has been for many years one of the physicians to the Children's Hospital.

The recently-issued articles of Senator on typhoid fever have attracted much attention here, where Brand's treatment by cold baths has never been very popular. It was claimed in Germany that this treatment had reduced the mortality to two per cent., or even as low as six-tenths of one per cent. at the military hospital of Straslund. These results have not been borne out by the experience of Senator, who confirms in many particulars the affirmations of Glæser at the Hamburg Hospital. Glæser had about $7\frac{2}{10}$ per cent. mortality with 868 patients treated by Brand's method, and almost identically the same with 939 patients, who underwent simply a treatment addressed to symptoms.

Senator's figures have not been quite so favorable. In the eight largest hospitals in Berlin, the mortality varies from $12\frac{1}{10}$ per cent. at the Augusta hospital to $19\frac{1}{10}$ per cent at the general city hospital of Fredericksein. At the Betanien hospital, where Brand's method was exclusively employed, the mortality was $13\frac{5}{10}$ per cent.

As regards the treatment of complications, the practice of Senator presents a few new features. In case of collapse with symptoms of heart failure he injects hypodermically one milligram of sulphate of strychnia three times daily, or camphorated ether, nine parts of camphorated oil to one part of ether. For intestinal hemorrhage, after repeated failures with the tincture of perchloride of iron and with opium, he has arrived at the conclusion that the best results are obtained from bismuth, in large and frequently repeated doses. For insomnia he counsels lukewarm baths, bromide of potassium and opiates.

Perhaps one of the most important works on medicine which have appeared here of late, is the Clinical Medicine of Prof. Germain Sée, who occupies Trousseau's chair at the Hotel Dieu.

The third volume has just appeared, and is devoted principally to the clinical consideration of asthma, the various congestive and inflammatory conditions of the lungs, and to diseases of the pleuræ.

To the study and treatment of asthma, M. Sée has always devoted considerable attention, and this part of the work will probably be more noticed than others.

This is how he understands asthma: "Any form of dyspnœa which originates in the structural alteration of any organ is not true asthma. Such a form of dyspnœa, accompanied or not by emphysema, is nothing more than a symptom, a pseudo-asthma.

"To this form belong the asthmatic attacks originating in cardiac disease.

"True asthma, as an independent disease, is always of nervous origin. It is always primarily a neurosis, always chronic and characterized by attacks which follow certain determined rules. This neurosis is of bulbar origin, having its seat in the respiratory centre and its origin in the exaggerated reflex sensibility of this organ."

As regards treatment, Prof. Sée is an active partisan of the iodine preparations. He employs iodine, iodide of potassium, and iodized ether. The iodide should be admintered in large doses, from fifteen to forty-five grains daily.

Iodine and its preparations, according to M. Sée, favor bronchial secretion, facilitate the reflex central act of respiration by regulating the functions of the respiratory centre, and also diminish the exaggerated sensibility of the respiratory mucous membrane.

Another important remedy is the newly-discovered product, pyridin, which probably forms the active principle in all the fuming

inhalations so commonly used in the treatment of the asthmatic attacks. Pyridin is also used as an inhalation, four or five grammes being placed on a saucer in a small room, and the patient remaining in the room for a length of time to inhale the vapor.

For the treatment of the attack, M. Sée is of opinion that hypodermic injections of morphia can frequently be used with benefit, but unfortunately they cannot be repeated for any length of time. A large proportion of this part of the work is devoted to the clinical experimentation and appreciation of the value of quebracho, belladonna and its derivatives, lobelia, arsenic, etc., in the treatment of the disease.

The two newest hypnotics, hypnone and urethan, have attracted considerable attention here, and have been experimented with largely by Dujardin-Beaumetz, Thechard, and Labbé. Dujardin-Beaumetz found that hypnone was very efficacious in producing sleep in some cases, while in others it failed lamentably; it seemed to be most successful in cases where the insomnia was of nervous origin, or accompanied with restlessness and a condition of extreme nervous erethism.

On the other hand, Filhen, at Erlangen, and Mairet and Combemalle, at Paris, report negative results from administration of the drug.

The other hypnotic, urethan, was experimented with principally in England, and has been found very serviceable in cases where persistent insomnia was experienced and the heart was diseased. In such cases where ordinary hypnotics can only be given with very great caution, urethan procured refreshing sleep for the patient without bad after-effects. The dose was generally about thirteen centigrammes.

At the last sèance of the Soc. de Therapeutique, M. Dujardin-Beaumetz strongly recommended muriate of cocaine in the attacks of gastralgia, sometimes so agonizing to tabetic patients; he uses a solution containing 50 centigrams of the muriate in 200 grams of water, giving a tablespoonful every second hour until the distress is relieved. The amelioration from the pain was rapid, but the patients complained of vertigo and dizziness.

The treatment of empyema came up for discussion at a recent séance at the Académie. M. Polaillon read the report of a case in M. Vaslin's service at the hospital at Angers.

The patient had three fistulæ, communicating with the pleura, which discharged a large amount of ill-smelling pus. He was much emaciated, the urine was albuminous, and there was every sign of approaching dissolution. M. Vaslin resected six centimeters of the sixth and seventh rib, made a large opening into the pleura and scraped its parietes with a dull curette, removing much false membrane. He then reclosed the wound, leaving two large drainage tubes in the pleural cavity. After five months, the fistulæ are now entirely closed, the side much depressed, and the patient may be considered cured. In the discussion which followed, M. Polaillon observed that cure was obtained in this case by comparatively a small amount of mutilation, but that this was due to the short duration of the sickness previous to operation. In a case of his own he was obliged to more thoroughly follow out the method of Estlander. He found it necessary to make a large opening, resect about fourteen centimeters of the seventh rib, twelve of the sixth, and eight of the fifth rib. The patient's condition, after all this mutilation, is somewhat ameliorated, but complete cure has not been obtained.

A curious case was reported at a recent séance of the Société de Chirurgie.

A young girl, fourteen years of age, presented herself in M. Despres' service at the Charité Hospital for a tumor, which had suddenly developed in the umbilical region. There was no pain, and nothing abnormal in any other part of the abdomen. It was deemed inadvisable to make any vaginal examination on account of the youth of the patient, and laparotomy even was considered after puncture with a fine trocar had revealed the presence of blood.

Fortunately for the young girl, a few days later a large flow of blood took place from the vagina, and subsequent vaginal examination revealed a very long conical os. It was simply a case of retained menses at an unusually early age. ***

Paris, February 13, 1886.

Hydrophobia,

Eds. Med. and Surg. Reporter:—

A timely article appeared in the Reporter for January 30th, bearing on the above subject, from the pen of Dr. Huddleson.

It has seemed to me ever since the Pasteur "craze," as some have termed it, commenced, the profession, as well as the people, have been pursuing an *ignus fatuus* that will lead them into swamps and sloughs of unreason. I do not expect to enter on a scientific dissertation on the pathology of hydrophobia, for I know nothing about it, and I never heard of any one who professed to know very much; and I also confess I know of no way

to distinguish a dog that has rabies from one that has not, and I know of no one who does. It does seem that all this talk about the Pasteur system is without warrant, for there is no reason to believe he has ever treated a genuine case of hydrophobia, because the disease was not developed in any one, and because no one knows whether any of the dogs were rabid. Besides that, sixty per cent. of those bitten by alleged rabid dogs are never heard from, and hydrophobia is just as likely to develop years afterward as months or weeks.

Who will undertake to say any of the Newark children would have died if they had not been inoculated by Pasteur? Outside of the sensational advertising obtained by certain metropolitan newspapers and doctors, the benefits, so far as any one can judge by results, have been absolutely *nil.* The results of post-mortem examinations on the bodies of persons dying of hydrophobia have been very unsatisfactory, and, so far as my knowledge extends, I think it would be impossible for the most expert surgeon to diagnose the cause of death in such a case, without antecedent knowledge.

Dr. H. has demonstrated the very slight analogy between small-pox and hydrophobia, and has given a very beautiful theory, and, I think, a correct one, of the *modus operandi* of vaccination; but can any one do as much for Pasteur's inoculation? We can all easily understand why vaccination or inoculation prevents, or at least mitigates, an attack of small-pox, because we believe it to be a disease produced by some poisonous matter in the blood; but I, for one, must confess my inability to understand how a portion of the spinal marrow of a rabbit which has previously been inoculated with a portion of the spinal marrow of a supposed rabid dog, inoculated a certain number of times and a certain number of days into the circulatory system of a human being, can prevent, or cure, a disease which affects the nervous system entirely, so far as our knowledge extends. The only disease which bears any strict analogy to hydrophobia is tetanus. Strychnia also produces effects somewhat similar, but a great many cases of tetanus recover without any special treatment, while it is doubtful if any one ever recovered from a genuine attack of hydrophobia.

In a score of years a man is likely to meet with one or more cases of every known disease; but in a practice of more than twenty years, I have never seen a case of hydrophobia, and never expect to. Pasteur, I believe, advises any one who may be bitten by a dog, to pen the animal up securely for a certain time, in order to know whether it is affected with rabies. This seems to me to "knock the bottom" out of his system, for while it is well known the poison lies dormant for months and even years in the human system, why may it not do likewise in an animal? In addition to this, why could not the disease develop in the dog even after the person or another animal has been bitten? Every dog that is seen running "amuck" through the country, snarling and snapping at anything on its way, is not mad.

From the well-known affection shown by dogs for their masters, it can easily be believed that a temporary separation from their human companions, as frequently happens, may worry them into a state of excitement sufficient to cause the cry of "mad dog," particularly if a dozen or two street *gamins* have been industriously following in the rear with stones, clubs, and wild shouts.

It is another demonstrable fact that all or nearly all the cases of hydrophobia of which we hear are caused by the bite from some pug or spitz that has never shown any symptoms of rabies, that has been kept as a household pet, that has bitten his master or mistress by accident apparently, while being fondled or fed. I have read of two such cases during the past week.

Whatever the poison is that causes hydrophobia, it must be introduced by means of the saliva, the teeth being the medium; but who knows where it comes from?—stomach, salivary glands, mucous membrane, or where? The fact that the mucous membrane is destroyed in patches to some extent after death from hydrophobia, proves nothing; neither does the amount of filth contained at times in the stomach; neither does anything else we know so far.

Suppose any of the Newark children should be bitten again, even admitting they are cured now, would a second journey to Pasteur, and more inoculations, be necessary? Or do they possess permanent immunity? Who can answer? Can Pasteur? As Dr. H. says, if this system of Pasteur's is correct, it will prove a priceless boon to humanity; and after it shall have been proven to be efficacious, none will more readily give him praise than I; but until that time comes I, like Dr. H., must, while not looking on him as a crank, believe he is wrong, and hope in the future some remedy or means of cure for this terrible disease may be discovered, even though Pasteur's should not be that remedy. W. F. Mitchell, M. D.

Addison Pa., February 27, 1886.

News and Miscellany.

State Sanitary Convention.

PRELIMINARY ANNOUNCEMENT.

The following circular which we have received from the State Board of Health explains itself:

A sanitary convention, the object of which will be to afford an opportunity for an expression of opinion on matters relating to the public health and the discussion of methods looking towards an advancement in the sanitary condition of the Commonwealth, the prevention of sickness and avoidable death, and the improvement of the conditions of living, will be held in Philadelphia, under the auspices of the State Board of Health, on Wednesday, Thursday, and Friday, May 12, 13, and 14, 1886.

The address of welcome will be delivered by His Excellency, Hon. Robert E. Pattison, Governor of Pennsylvania.

The following will be among the subjects that will be discussed by prominent sanitarians:

1. The Sanitary Needs of School Buildings and Grounds.
2. The Water Supply of Towns and Cities.
3. The Water Supply of Philadelphia.
4. The Disposal of Slops, Garbage, Refuse, etc.
5. The Prevention of Communicable Diseases.
6. The Influence of Clothing on Health.
7. Ventilation.
8. The Drainage and Sewerage of Cities and Towns.
9. The Drainage and Sewerage of Philadelphia.
10. The Influence of Diet on Health.
11. The Relations of Christianity to Health.
12. Mistakes in School Architecture.
13. Defective Vision in School Children: Causes and Management.
14. The Necessities of Physical Education.
15. Drainage and Sewerage in Country Districts.
16. Sanitary Science in Villages.
17. Municipal Sanitation.
18. Artificial Feeding of Infants.
19. Condensed Milk.
20. Various Artificial Baby Foods.
21. The Inheritance of Disease.
22. Hygiene of the Home.
23. Sanitary Plumbing and Drainage.
24. Tests for Impurities in Water: The Use of Filters.
25. Germicides.
26. Vaccination.
27. The Hygiene of Old Age.
28. Cholera.
29. City *versus* Country Life, from a Hygienic Point of View.

The public are cordially invited to take part in and help to make a success of this convention.

At a later date, a circular of details will be issued.

Joseph F. Edwards, M. D.,
Chairman Committee of Arrangements,
224 S. 16th St., Philadelphia, Pa.

Adulteration of Lard.

The *National Druggist* tells us that lard is occasionally subjected to scandalous adulterations. It contains not infrequently a large quantity (25 to 30 per cent.) of starch. Furthermore, 10 to 20 per cent. water, 2 to 3 per cent. alum, and about 1 per cent. lime have been found in lard. Unfortunately, mere inspection will not enable us to determine whether lard contains water or not, for the water is united in such a way that the lard is white and odorless. If, however, lard which is adulterated with water is heated in a pan, it soon begins to sputter, while pure lard melts quietly and without formation of bubbles. If lard is melted in a test-tube over an alcohol flame, pure unadulterated lard yields a clear, transparent, faintly yellowish fluid; poorly cleaned lard shows floating fibres of meat or shreds of connective tissue, while mechanically suspended mineral substances which were worked in to increase the weight, fall to the bottom as a deposit. Water is often added as an adulterant. To determine the percentage of water, weigh 50 grams of lard in a tared beaker-glass, and place for one or two hours in a water bath. The water is separated gradually from the lard and sinks to the bottom. On cooling, a hole is made through the lard, and the water allowed to flow out, when the loss of weight determines approximately the amount of water. The water is to be submitted to a further examination, for, in order to facilitate the mixture of the water and fat, soda (carbonate of sodium), potassa (carbonate of potassium), or lime, is often used, which saponifies a small part of the fat, and the soap brings the fat into more intimate mixture with the water. In such a case the fat would have alkaline reaction, *i. e.*, a strip of red litmus paper is colored blue. If lime was used as an adulterant, the water will yield a white precipitate on the addition of a few drops of

solution of oxalate of ammonium. Lard, which is viscid, fluid, ropy, or mixed with fibrous substances, is to be considered as bad or as mixed with inferior fats. Lard is also often mixed with grease, which latter is characterized by being less white and of less uniform consistence, besides having a peculiar salty and disagreeable taste.

Balata.

An interesting report made by Government Botanist G. S. Jenman, Demerara, on the balata industry in British Guiana, is published in part in the *Pharm. Jour. and Trans.* for September, 1885. Balata is the concrete milky juice of Mimsops globosa (*Gaertner*), a large, hard-wooded forest tree, sometimes reaching 120 feet in height, and found ranging from Jamaica and Trinidad to Venezuela and French Guiana. Balata has never found its way into commerce in any considerable quantity, though it has always been highly spoken of. It is intermediate in character between India-rubber and gutta-percha, combining the properties of both, and for certain purposes is better adapted than any other of the natural caoutchouc substances. "Its strength, also, is very great, and, as it does not stretch under tension, for special appliances, such as bands for machinery, it is unequalled. It has recently been pronounced by an American firm of manufacturers as the 'best gum in the world,' and that it has not had a greater success is due more to the hitherto limited supply than to any defect of quality intrinsically in itself." This opinion is fully borne out in a report by Dr. Hugo Muller, F. R. S. It is to be regretted that the methods of obtaining the juice by tapping, either standing or after felling, are calculated to seriously reduce the number of these valuable trees.

The Arsenic Habit—A Remarkable Case.

Dr. T. D. Crothers reports, in the *Quarterly Journal of Inebriety* for October, a remarkable case of the arsenic habit. The patient, an English horse-jockey, had led an irregular life, and had probably drank considerably. He began to take arsenic about the year 1875, using it for the purpose of keeping off fevers. For five years he took from one to two drachms of Fowler's solution daily, and his general health continued good. From this time he gradually increased the dose until he was taking from twelve to twenty grains of arsenic daily (!), either in the form of the powdered acid or of Fowler's solution. When seen in 1885, his appearance was that of good health, the face full, the skin clear and white, the eyes brilliant but unsteady, cutaneous sensibility was diminished, the appetite was poor, the action of the bowels irregular, and the heart was enlarged. There was no muscular weakness, but the gait was slow and hesitating.

Lager Beer.

In the *Med. Summary* we read as follows: "We often hear physicians say, 'Take a glass of beer; it will assist digestion and produce sleep.' The remark shows that physicians as a class are poor chemists, although they study that science at college. Of all the *villainous* mixtures which man takes into his stomach, lager (laying) beer is the most injurious. The lager beer sold in our large cities is not *beer* at all, but a chemical mixture of water, alcohol, soap, aloes, and cannabis indica of a low grade.

"The beer-drinker is always subject to Bright's disease with and without dropsy, and the chronic beer-drinker is a most pitiable object, and made up of bloat and acne rosacea. No conscientious physician should recommend beer."

Arsenical Wall-Papers in Malarious Regions.

In a recent number of the *Gentleman's Magazine*, Mr. Matthieu Williams suggests the use of the generally-regarded injurious arsenical wall-papers in malarious regions. He says: "I maintain that the hotels in the vicinity of the Campagna, the Pontine Marshes, the Maremma, and other malarious regions of Italy, should be papered throughout with brilliant green arsenical papers, and painted with Scheele's green or other arsenical pigment. The same should be done in New Orleans, and all other such places, for the special benefit of (non-acclimatized) visitors." Perhaps hotel proprietors in malarious regions will wish to hear from other sanitary authorities before adopting the novel suggestion.

Dr. Ramsey's Revolver.

Officer George F. Alstadt, of the Pittsburgh police force, has in his possession a revolver which he thinks may have been stolen from its owner, and desires it to be returned if so. It has the following inscription on the metal on front of handle: "Presented to J. Allen Ramsey, M. D., Surgeon 3d Brigade P. V., by his friends.

Items.

—In the *Brit. Med. Jour.*, Dr. George J. Robertson reports a case of extra-uterine pregnancy, and death of the fœtus at four months, intestinal obstruction from pressure, removal of the fœtus by perineal section, and recovery.

—"Have you heard about Blicker?" "No; what's up now?" "They say he's struck natural gas." "Natural gas! Well, I should think so! He's married a widow who talked three men to death before she was forty."

—Dr. P. Marie, one of the physicians to La Salpetriere Hospital in Paris, says in *Le Progres Medical* that ovarian tenderness is frequently met with in chorea minor, and that it is always situated on the side where the movements first showed themselves.

—A New York physician boasted at dinner that he had no fear of trichinæ, because he cured his own hams. "Well," said a lady guest to him, "I think it would be preferable to be your ham than your patient." The doctor fled to Germany.

—Vogel relates the following in his "Diseases of Children": "I once treated an American lady, who still suckled her son, who was *two and a half years old*, till one morning, when the strongly-developed, robust child was called to be nursed, he very kindly replied: 'I thank you, dear mamma, the nursing is too tedious for me.'"

—The late Professor Laycock was very fond of drawing attention to hereditary peculiarities. One time, in the middle of a lengthened exposition of the features in common of a mother and child, the woman, perhaps a little uneasy, stopped him, saying, "A weel! I'm no the bairn's mither, I'm just his step-mither."

—An English judge strongly affirms that a medical man should not leave a woman in labor, except his life be in peril; that if he desires to abandon the case he must tell the friends to get another doctor, and remain with the woman till the doctor arrives. If he does otherwise than this, he will be responsible before the law for such injury as may happen to the woman from want of medical attendance.

—According to Dovodtchikoff, naphthalin is an invaluable dressing for ulcers. He writes in the *Vrach*, that it is inexpensive and easily used, therefore of great service to poor people. After its application, granulations quickly appear, and cicatrization is rapid; its antiseptic properties serve to remove false membranes and bad odors. Naphthalin dressings do not irritate ulcers, nor produce any pain, and patients can continue their avocations without any difficulty.

OBITUARY NOTICE.

AUSTIN FLINT, SR., M. D.
